Treatment of Gas Casualties.—Sir JOHN ANDERSON stated on November 24 that specially selected and trained medical practitioners were appointed by the Home Office in 1936, and were available throughout Great Britain to give to members of the medical and allied professions, whether they had volunteered for air raid precautions duties or not, free training in the general and medical aspects of anti-gas methods so as to enable them to give skilled treatment to gas casualties.

Notes in Brief

It will not be possible to legislate this session to give effect to the recommendations of the Departmental Committee on Coroners.

The committee appointed to consider the effect of cardroom dust on workers in the cotton industry hopes to present its report before the end of this year.

The administrative cost of health insurance during 1937 was 14.6 per cent. of the total expenditure on that scheme.

Ample fresh vegetables are included in the diet of H.M. prisons, but the inclusion of fruit would involve a large addition to the cost, and the medical evidence as to the effect on health of the present dietary is such that the Prison Commissioners have not felt justified in proposing this increased expenditure.

Medical News

The Harben Lectures, 1938, under the auspices of the Royal Institute of Public Health and Hygiene, will be delivered by Professor R. D. Passey on "Factors in Carcinogenesis" at 28, Portland Place, W., on Monday, Tuesday, and Wednesday, December 5, 6, and 7, at 4 p.m. Admission is free to members of the medical profession and to medical students. Applications for seats should be made to the secretary of the Institute.

The next Réunion Médico-Chirurgicale de Morphologie will be held in the amphitheatre of the School of Anthropology, 15, Rue de l'Ecole-de-Médecine, Paris, on Wednesday, December 14, at 9 p.m. Particulars may be had from Dr. C. Claoué, 39, Rue Scheffer, Paris, XVIe.

The fifty-first Congress of the German Society for Internal Medicine will be held at Wiesbaden under the presidency of Professor Stepp of Munich from March 27 to 30 next, when discussions will be held on arteriosclerosis, morbid anatomy of circulatory disturbances in the brain, clinical disorders of the brain, and psychical changes due to disturbance of the cerebral circulation.

The programme has now been issued for the twelfth annual congress of the British Institute of Radiology to be held at the Central Hall, Westminster, on December 7, 8, and 9. On the first day, at 3 p.m., the Mackenzie Davidson memorial lecture will be given by Dr. G. Shearer. On the second day there will be medical papers on "Contact Therapy" in the morning, and physical papers in the afternoon. On the third day there will be medical papers on "X-Ray Diagnosis with Reference to the Urinary Tract" and on "Stereo-radiostriatigraphy" in the morning, and the Silvanus Thompson memorial lecture by Dr. Ledoux Lebard on "Advances in the X-Ray Diagnosis of Gastric Cancer" in the afternoon. An exhibition of x-ray apparatus will be open each day.

Major-General Sir Cuthbert A. Sprawson, I.M.S.(ret.), who visited the U.S.S.R. this summer, will speak on his impressions at a meeting arranged by the Society for Cultural Relations on Thursday, December 8, at the Royal Society of Arts, John Street, Adelphi, W.C., at 8.30 p.m., with Professor W. E. Le Gros Clark, F.R.S., in the chair. The secretary of the S.C.R. will send invitations to those interested if they apply to her at 98, Gower Street, W.C.1. Sir Cuthbert Sprawson will deal principally with Soviet medical education and the campaign against tuberculosis.

At the first meeting of the trustees of the Lord Nuffield Fund for Orthopaedic Services in the Union of South Africa, held in London on November 22, the Earl of Athlone was elected chairman and the trust deed was signed by Lord Nuffield and the four trustees—Lord Athlone, Professor G. R. Girdlestone, F.R.C.S., the High Commissioner for South Africa; and Mr. W. Hobbs. The other trustees, in approving Professor Girdlestone's draft orthopaedic scheme for the Union of South Africa, place on record their appreciation of his valuable services in undertaking the great burden of work involved in its preparation and his zeal and generosity in giving to South Africa the benefit of his great experience and advice.

With the November number Dr. John Comrie has succeeded Dr. A. Rae Gilchrist as editor of the *Edinburgh Medical Journal*.

The Crown Agents for the Colonies, 4, Millbank, London, S.W.1, have published at 6d. the returns for 1937 of vital statistics of non-native officials in West Africa.

EPIDEMIOLOGICAL NOTES*

Infectious Diseases during October

In the four weeks ending October 29, 1938, 7,558 cases of scarlet fever, 5,227 cases of diphtheria, 2,050 cases of primary pneumonia, and 111 cases of enteric fever were notified in England and Wales. The notifications of scarlet fever, diphtheria, primary pneumonia, and enteric fever were 74 per cent., 102 per cent., 72 per cent., and 62 per cent. of the expected numbers (deduced from the median values of the corresponding weeks of the years 1929-37).

Enteric Fever

The outbreak of typhoid fever in Shoreditch, described in detail in last week's issue, appears to be under control (last case notified on November 24), despite the fact that the source of infection has not been traced so far. Of the 28 cases notified to date, 25 were in the borough and 3 were 'outside'. As 2 of the cases have not yet been confirmed the actual total is 23 cases in the borough. In East Suffolk 4 cases were notified during the week—3 at Hartismere and 1 in Ipswich.

Poliomyelitis

During the week poliomyelitis fell in England and Wales from 51 to 45, but in London notifications rose from 3 to 5. Of the 45 cases 4 were in Essex (West Ham 1, Halstead 1, Chelmsford 1, Saffron Walden 1), 4 were in Southampton (Ringwood and Fordingbridge 2, and 1 each in Eastleigh and Winchester), 3 in Hereford (Bishop's Stortford 2, Welwyn Garden City 1), and 3 in Derby—all in Heanor urban district. The 5 London cases occurred in Battersea, Finsbury, Greenwich, Lambeth, and St. Pancras.

In Germany in the week ended November 5 there were 254 cases notified, compared with 96 for the corresponding week of 1937. Increases were recorded in Bavaria 61 (41) and Württemberg 51 (36). Twenty-one cases were notified in Holland during the week ended November 12, 14 of these being in the Province of South Holland and 4 in that of North Holland. During the fortnight ended October 31, 117 cases were recorded in Sweden, including 32 non-paralytic cases: of these 117 cases 32 occurred in the rural districts

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

of Jämtlands Province and 19 in those of the Västernorrlands Province. During the same period 89 cases were recorded in Finland, including 18 in the rural district of Hollola and 12 in the town and district of Helsingfors.

Anthrax

The manner in which public health authorities, with the co-operation of hospital and pathological services, and the business firms immediately concerned trace and eradicate even rare infections is well illustrated by a recent case of anthrax in the borough of Southwark, London. On October 21 a workman employed in a brush-making factory developed a pimple on the face which was recognized as a malignant pustule when he came under observation five days later: serum treatment was immediately instituted with complete success. Specimens of all types of bristles and hair were taken from the factory for examination at the Ministry of Health pathological laboratory in London: among these was a specimen of Manchurian horsehair which had been purchased from a firm in Bermondsey on October 3 and which was said to be dusty and dirty. Similar specimens were obtained from this firm and from the original source of supply, acquired in October, 1937, by a firm in the City of London. None of this horsehair had been used by the brush factories until October 3, 1938. The distribution of the suspected horsehair was therefore limited, as was the number of brushes already made from it. All the firms handling the bristles and horsehair and all brush manufacturers were asked to stop all sales until the investigations were completed. Lists were prepared of all purchasers, retail and private, of the horsehair, bristles, and brushes, and the medical officers of health for the districts concerned were notified. On the evening following notification all the suspected articles had been traced. Next day the Ministry of Health laboratories reported that the hogs' bristles were apparently free from infection but the Manchurian horsehair was infected. Medical officers of health were all informed by telephone, and late that evening all the infected hair and brushes in the districts concerned were destroyed.

Diphtheria and Scarlet Fever

During the week diphtheria rose from 1,445 to 1,530 in England and Wales, and from 141 to 160 in London. The chief centres affected were London 160 (Lambeth 20, Battersea 13, Wandsworth 12, Southwark and Poplar 10 each, and Paddington and Shoreditch 8 each), Birmingham 33, Bristol 31, Manchester 27, Liverpool 25, South Shields 24, Sheffield 21, Easington 17, and Cheltenham 10. In South Shields diphtheria is still rife, but the type of disease has become milder, many of the cases notified being merely carriers. Nearly 5,000 children between the ages of 5 and 8 years have recently been inoculated, but it will probably be found necessary to apply the measure to children under school age before the disease can be eradicated.

Scarlet Fever

Despite the increase of scarlet fever in England and Wales from 1,887 to 2,072, notifications remain well below the median value for the last nine years, and this holds true for London to a much greater degree. The principal towns affected were London 179, of which 16 were in Wandsworth, 11 each in Bethnal Green, Camberwell, and Hammersmith, and 10 in Hackney; Birmingham 41, Liverpool 66, Manchester 46, St. Helens 23, Stoke-on-Trent 30, Leeds 32, Sheffield 32, Bradford 20, York 20, and Newport 16.

Primary and Influenzal Pneumonia

In England and Wales pneumonia (influenzal and primary) fell from 799 to 723, a figure that is well below the median value for the last nine years. In London a slight rise is recorded, and the number is a little above the median value. Deaths fell from 28 to 21. The counties chiefly affected were: Warwick 41, of which 31 were in Birmingham, West Riding of Yorkshire 85 (Sheffield 17, Leeds 16, Bradford 10), Durham 38, and Stafford 32.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 19, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.
† Death from puerperal sepsis.

Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitology
Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Éireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Bacillus, Dublin; telephone 62550 Dublin.)

QUERIES AND ANSWERS

Condensation Water from Theatre Skylight

Dr. E. S. HEMSTED (Newbury) writes: As some of your readers have probably had to solve a similar problem, I should be glad to have the benefit of their experience. The operating theatre in a nursing home is provided with extra lighting by a V-shaped skylight over the operating table. In cold weather the heat of the theatre causes condensation on the glass and drops of water fall from time to time on the patient and also on those carrying out the operation. An electric fan working in the skylight fails to keep the air sufficiently disturbed to prevent this condensation. This difficulty must be frequently met with, and if any reader can suggest a sure and simple solution it would be very greatly appreciated.

Local Use of Petroleum

Dr. RHYS PATON writes: Ordinary lamp paraffin is often used as a hair restorative and it appears to be effective. Can anyone tell me if it is carcinogenic if used over a period of years?

** We have referred this matter to an expert adviser, who informs us that lamp oils distilled from ordinary petroleum crude have not been tested for carcinogenic power but only those from shale. As the latter proved to be non-carcinogenic, and in view of the generally lower activity of products of petroleum crudes compared with products of oil shale, it is fairly safe to assume that ordinary lamp paraffins are for practical purposes non-carcinogenic.

Cattle Ringworm in Man

Dr. P. J. SMITH (Co. Cork) writes: Dr. Stewart (*Journal*, November 12 (p. 1027)) will find ung. hydrarg. nitr. dil. well worth a trial for cattle ringworm in man. I am also a medical practitioner in an agricultural area, and I find that a daily application of this ointment is a specific remedy for the disease he mentions.

Dr. C. EDE writes: I was faced with the same problem when I started practice in a large dairying district many years ago. Dr. Scqueira came to my rescue with resorcin 5j, tinct. benzoin. co. 3j. This should be painted all over the area twice a day for a week or ten days.

Varicose Veins

Dr. STUART MCAUSLAND (Liverpool) writes: It is probable that "M.E.D." gave the injection by the full vein method. There are some varicose veins which do not sclerose when the fluid is injected into the full vein. The use of a tourniquet in the empty vein method is desirable. When one fluid

failed, "M.E.D." should have had recourse to one of the other sclerosing fluids—for example, 5 or 10 per cent. sodium morrhuate, or lithium salicylate 35 per cent. with 1 per cent. ethocaine. Other reasons for the failure may be that the dose was inadequate or that "M.E.D." did not firmly occlude his puncture site, and exert constant pressure on the vein after the injection by means of a pad of wool and firm strapping with elastoplast. Actually, in my own clinic, no one fluid constantly acts as a sclerosing agent. In such cases one adopts Rodney Maignot's mixed fluid method. This consists in injecting into the one vein 4 or 5 c.cm. of lithium salicylate and 2 or 3 c.cm. of quinine. These fluids when mixed are incompatible, and cause the formation of a glutinous substance. This injection can be made from two separate syringes through one large needle, or a second puncture of the vein may be made half an inch from the original puncture. Upward and downward flushing of the vein is also helpful. Full details of the technique will be found in my book, *Cure of Haemorrhoids and Varicose Veins* (John Bale Sons and Danielsson).

LETTERS, NOTES, ETC.

Price of Radium

In the article in last week's *Journal* headed "Government versus Cancer" we recorded an announcement in the *Times* that the Government had bought 11 grammes of radium from the Eldorado Gold Mines, Ltd., at a cost of about £200,000. As we were aware that radium can be bought for about 15 a milligramme we should have interpolated the convenient "(sic)" or expressed surprise and doubt with the aid of an exclamation mark. But we did not know which figure was wrong—that for the price paid or that for the quantity bought. During the war radium cost about £20 a milligramme; eight or nine years ago it cost about £12 a milligramme; during the last four or five years the price has been in the region of £10; and during more recent months between £5 and £7.

"Typhoid Mary"

Dr. W. R. BETT writes from New York City: Mary Mallon or "Typhoid Mary" (typhoid carrier No. 36), to whom reference was made in the *Journal* of June 4 (p. 1247) and on August 20 (p. 436), died of paralysis on November 11 in Riverside Hospital on North Brother Island in New York City's East River. A "medical prisoner" for more than a quarter of a century, at first she had proved rebellious and moody, but with advancing years became profoundly religious and more philosophical in her acceptance of fate. She suffered a paralytic stroke on Christmas Day, 1932. Of Irish extraction, she managed to conceal her exact age, but was believed to be about 70. She was buried in St. Raymond's Cemetery, the Bronx.

Reprints and Pamphlets

The Librarian, University College, Dublin, would be pleased to receive offprints and pamphlets on medical subjects for the use of the staff and research workers in the Medical School of that College. The Medical Library already possesses a large collection, but it is very probable that much material on these subjects is still available.

Ether Convulsions

Dr. J. J. HOGAN (Waterford) writes: Seeing the amount of correspondence that has appeared on ether convulsions, I thought it might interest the writers and other anaesthetists if I mentioned that I have been giving ether for thirty-two years (about 20,000 cases) and I have never seen a case of ether convulsions.

Benzedrine: Correction

Dr. G. DE M. RUDOLF writes: So seldom are errors made in the reports in your columns of discussions at the Royal Society of Medicine that I would like to draw attention to one which must be the exception which proves the rule. In the account of the discussion on benzedrine (November 5, p. 961) I am reported to have said that I knew a doctor who used an inhaler about once an hour and was awake all night. Perhaps I lowered my voice so that the reporter was unable to hear, but I said that he used the inhaler more often than once an hour, and that he used it in the evening. I am drawing attention to this point as, in my experience, the inhaler used hourly, even in the evening, does not interfere with sleep.

Quintuplets.—Two unrecorded cases of quintuplet births are described, bringing the total number of authentic cases in medical literature up to forty-seven. The Canadian quintuplets, three girls and two boys, were born in 1880, and the Italian, three boys and two girls, in 1914.

Leber's Hereditary Optic Neuritis.—In the family under consideration here Leber's hereditary optic neuritis had affected twenty-three males in six generations. The condition is usually symmetrical, and is a sex-linked malformation of the optic nerve with atrophy of the papillomacular bundle transmitted by the female to the male.

Slipping Rib.—Recurring luxation of a costal cartilage, or slipping rib, is a condition which is often overlooked. The pain which it causes is frequently attributed to conditions of major importance in neighbouring organs. The authors have met with eight cases of slipping rib during the past five years, of which four are described in detail. The method of treatment is outlined.

- *Tannin in Thoracoplasty. E. Leubet and J. Maresca.—p. 591.

Tannin in Thoracoplasty.—Five possible modes of costal reossification following thoracoplasty are described, together with their results and inconveniences. For its prevention, chemical applications in the course of a subperiosteal operation are preferred to the extraperiosteal resection. Formalin is sometimes dangerous and not always effective, but the authors, on the basis of experiments in dogs and in two patients (described in detail), recommend the application of 20 per cent. tannin in dilute alcohol as sufficiently retarding bony regeneration without injuring the tissues. The advantages of performing thoracoplasty in several stages are discussed.

 Physiology of Vitamin C. C. King.—p. 1095.

Anorexia Nervosa.—Farquharson and Hyland are of the opinion that cases of anorexia nervosa should be treated in the public ward of a general hospital. After careful examination the patient should be assured that there is no organic basis for the symptoms. She should be encouraged to eat at frequent intervals small but increasing quantities of food of high caloric value. This must be calculated daily until 3,000 calories are being taken, when the number of meals is decreased and the variety of food increased. The relationship between emotional disturbances and imbalance of the autonomic nervous system should be explained. Prolonged

psychotherapy may be necessary to make the patient understand the true nature of her illness and to enable her to become properly adjusted to those disturbing associations in her daily environment from which there is no escape.

Case of Pneumococcal Meningitis treated with M & B 693. K. Robertson.—p. 728.

Sulphanilamide and Leucocytes.—Reports of occasional fatalities from agranulocytosis following the administration of sulphanilamide prompted the authors to perform serial leucocyte counts in fifty ambulant female patients each receiving 21 grammes of sulphanilamide in fourteen days. A transient polymorphonuclear leucopenia was found in 46 per cent., and in 44 per cent. a monocytosis—usually between the seventh and twentieth days. The toxic symptoms—generally mild—were noted in 70 per cent. of these cases are analysed.

Toxic Goitre.—This is a comprehensive study of 450 consecutive patients with toxic goitre, most of whom were treated by a one-stage subtotal thyroidectomy, with an operative mortality of 0.6 per cent. Of these cases 208 had been followed up for more than four years. In this group a complete restoration of economic usefulness was obtained in 85.7 per cent. and partial restoration in 8.3 per cent., while the end-results were unsatisfactory for various reasons in 6 per cent.

*Psychiatric Examination of Prostitutes in Copenhagen, with Special Reference to Mental Hygiene Measures. G. V. Bredmose—p. 1456.

Psychiatric Examinations.—The publication in March, 1936, of Dr. Tage Kemp's monograph on the causes of prostitution has inspired the institution of arrangements for the systematic psychiatric examination of prostitutes arrested by the Copenhagen police. Bredmose's study deals with seventy prostitutes thus examined between April, 1936, and April, 1938. It shows how important a part a psychiatric examination may play in dealing with this problem.

Presse Médicale

Paris vol. 46 September 21, 1938

- *Vascular Therapy in Aortic and Mitral Insufficiency. A. Ferrannini—p. 1401.
*Gangrene of Limbs of Venous Origin. M. Audier and H. Halmovici—p. 1403.
*Role of Vitamin B₁ in Humoral Regulation of Nervous System: Therapeutic Considerations. B. Minz—p. 1406.

Vascular Therapy in Heart Disease.—Ferrannini claims that great harm is sometimes done, in mitral or aortic insufficiency,

by the administration of remedies such as digitalis and strophanthin. They act in the same direction as the lesion and thus tend to intensify its effects—for example, in aortic insufficiency these drugs tend to increase diastole and to intensify systole, thus raising the systolic and reducing the diastolic pressure and aggravating the already excessive pulse pressure. He therefore prefers to use general tonics in conjunction with various physical methods, of which he gives a detailed list.

Venous Gangrene.—The authors discuss the problem of gangrene of the limbs of venous origin from the historical, clinical, pathological, and experimental points of view. They come to the conclusion that four chief factors are involved in these cases: (1) arrest of the circulation; (2) venous stasis; (3) vasomotor disturbances; and (4) certain general conditions, such as infectious diseases, tuberculosis, cachexia, etc.

Vitamin B₁ and the Nervous System.—The author discusses the role of acetylcholine in the regulation of the nervous system, and claims that the destruction of this substance by the esterase in the tissues (which can be partially inhibited for a short time by eserine) can be effectually prevented by vitamin B₁, which reinforces the action of acetylcholine without interfering with the esterase mechanism. Minz points out the significance of this fact for the treatment of certain nervous diseases.

- *Extracutaneous Localization of Myxoedema. G. Marañon—p. 1417.
*Malaria as Parasitic Disease of Reticulo-endothelial System. G. Sicault and A. Messelin—p. 1419.

Extracutaneous Myxoedema. Marañon states that there is no *a priori* reason why myxoedema should be confined to the subcutaneous tissues. He then proceeds to give instances of myxoedema affecting the mucosa of the nose, pharynx, and larynx; that of the digestive canal from the mouth to the anus; that of the vulva and vagina; the heart, liver, and kidneys; and also the nervous and locomotor systems.

Malaria.—The authors, who are in charge of the French anti-malarial service in Morocco, explain their reasons for believing that malaria is primarily a disease of the reticulo-endothelial tissues and only secondarily a disease of the blood. They also show the bearing of these views on the treatment and prophylaxis of malaria.

***The Scandinavian Disease. J. Christensen—p. 1054.

"The Scandinavian Disease."—Johanne Christiansen found in Berlin that agranulocytosis following the administration of amidopyrin preparations was referred to as "the Scandinavian disease." She has come to the conclusion that the "pyramidon-terror" is strictly limited to Scandinavia, and to Denmark in particular. She suggests that the faulty nutrition of her countrymen may give rise to allergic susceptibility to otherwise harmless substances.

 *Carcinogenic Activity, Structure, and Chemical Reactivity of Polynuclear Aromatic Hydrocarbons. L. F. Fieser.—p. 37.

Carcinogenic Hydrocarbons.—In the first part of this long critical review Fieser deals with the activity of the three best-known carcinogenic hydrocarbons (1:2:5:6-dibenzanthracene, 3:4-benzpyrene, and methylcholanthrene) and discusses the influence of the physical condition and dosage of the administered material, and of the species, strain, age, and sex of the animal upon the carcinogenic response. The second part provides information about the commercial sources of the same three hydrocarbons and the methods of preparation and purification. The third part contains a discussion of the relationship between chemical structure and carcinogenic activity, and the concluding part deals with the fate of carcinogenic hydrocarbons in the body, and with chemical properties and reactions which may be significant in regard to the carcinogenic activity.

 Paroxysmal Haemoglobinuria with Case Report. A. C. Woolter and B. S. Parks.—p. 402.
 Pericarditis with Effusion complicating Tularemia. D. D. Stoffer.—p. 407.

Coronary Artery Disease and Angina Pectoris.—The clinical pictures and the pathological findings in the various types of coronary artery disease and angina pectoris are reviewed and correlated. The differential diagnosis of atypical clinical forms of the conditions is discussed and the value of the available remedies considered.

Mechanism of Temperature Regulation.—An account is given of recent work on the balance between heat production and heat loss in the body. The importance of the part played by the factors concerned in heat loss in differing external conditions is indicated, and the importance of shivering, or tensing of the muscles, in accelerating heat production is stressed.

Very Unusual Case of Subcutaneous Emphysema caused by Foreign Body. L. Daily.—p. 831.
Sternal Subcutaneous Operation without Nasal Pack. A. C. Howe.—p. 836.
Case of Streptococcal Meningitis with Streptococcaemia: Recovery. A. Lewy.—p. 839.

Intranasal Medication.—There appears to be an increase in the incidence of so-called "lipoid pneumonia," a chronic lung condition which results from the prolonged use of oily sprays for nose and throat conditions. The authors studied in the lungs of rabbits the early changes which followed intranasal instillation of oils and watery solutions of antiseptics, astringents, and vasoconstrictors. The most suitable vehicle for intranasal medication is isotonic salt solution, as it causes no interference with ciliary activity. The mild silver proteins cause no apparent harm to ciliary activity, but their antiseptic value is doubtful.

Sublingual Epidermoid Cysts. B. R. Shore.—p. 305.
Regeneration of Sensation in Transplanted Skin. H. R. McCarrroll.—p. 309.

Heparin in Thrombosis.—Purified heparin is non-toxic, both in animals and humans, and may be employed clinically in cases such as embolectomy and arterial suture where intravascular clotting presents a problem. Its use as a prophylactic against post-operative thrombosis is discussed. (See also *Journal*, November 12, p. 977.)

Communicating Hydrocephalus.—This is a description of the technique of additional procedures, such as removal of the plexus of the body of the lateral ventricles and fourth ventricle, which may be employed in cases in which removal of the glomus alone is insufficient to effect a cure.

Pancreatic Reflux.—The presence of amylase in the common bile duct is an index of pancreatic reflux. The common duct appears to be unaffected by the presence of pancreatic ferments, but these may cause acute cholecystitis in the gall-bladder.

Case of Blastomycosis Pustulenta Profunda. A. Dosa.—p. 743.
Effect of Acid and Alkaline Diet on White Blood Cells in Skin of Mice. H. Trill.—p. 747.

Fever Therapy of Animal Syphilis.—The author discusses the rationale of the malarial treatment of neurosyphilis and the suggestion that the beneficial effects are mainly due to induced fever rather than to malaria *per se*. Fever is believed to produce its effect by stimulation of the production of immunity. He reviews the literature on the treatment of animal syphilis by artificially induced fever, and describes his own experiments. He concludes that fever alone is not effective in healing the lesions of rabbit syphilis, but that the action of salvarsan is reinforced by the addition of fever, especially when the two treatments are given on the same day.

Chemotherapy of Gonorrhoea.—The chemical composition of some derivatives of sulphanilamide and some facts and theories as to their action on the gonococcus and gonococcal infections are discussed. It is suggested that these preparations have a double action in arresting the growth of the organism and stimulating the defences of the host by an effect on the reticulo-endothelial system.

Primary Carcinoma of Lung: Clinical and Pathological Study of 100 Cases. S. Koltelsky.—p. 636.
Gastro-enterology: Review of Literature from January, 1937, to June, 1938. C. M. Jones, T. V. Umy, E. B. Benedict, M. H. Clifford, and B. V. White.—p. 652.

Digitalis in Heart Failure.—Digitalis decreases the size of the heart and increases ventricular contraction. In the normal heart the decrease in size of the cavity of the ventricle, by reducing the capacity of the heart, reduces the cardiac output. In the diseased enlarged heart the decrease in ventricular capacity is relatively unimportant, and the effect of digitalis in increasing ventricular contraction is shown by an increase in cardiac output.

Formation of Gall-stones.—Gall-stones are common in the ox and hog but do not occur in the sheep and dog; human gall-stones placed in bile from the latter animals are dissolved. This solvent capacity appears to be related to the fatty acid content. Human bile has a very low content of fatty acids. It is suggested that the fatty acids of bile play a more important part in maintaining cholesterol in solution than do the bile acids.

- Thalamic Dysfunction: Report of Case in which Thalamic Syndrome was treated by Excision of Porencephalic Cyst H. L. Kozol.—p. 352.

Pathology of Schizophrenia.—Elvidge and Reed have studied the oligodendroglia in cerebral tissue removed at biopsy by brain puncture. Using silver impregnation methods they found swelling of the oligodendroglia in the white matter in cases of schizophrenia and manic-depressive psychosis. They suggest that these changes may indicate massive physiological disturbances in the associational and commissural pathways of the brain, and that a causal toxic or metabolic factor may be present in the psychotic state.

Sweat Secretion.—In their third article on sweat secretion List and Peet have studied the sweating produced by pilocarpine and mecholyl, especially with regard to the site of action of these drugs. Observing the responses in different nerve lesions, they conclude that these drugs stimulate the endings of cholinergic nerve fibres and that the sweating is not centrally produced.

Intercellular Substance of Cerebral Cortex.—Using the dark-field microscope, Tait has made observations on the intercellular substance of the cerebral cortex. Its physical and physiological characteristics are analogous to those of serum protein. It furnishes an embedding material for the cortical cells and is altered in pathological conditions, especially dementia paralytica, in which it is thinned and diminished in amount.

Archives of Otolaryngology

- Congenital Dermoid Cyst and Fistula of Dorsum of Nose. E. W. Hagens.—p. 399.
- Bilateral Acoustic Neurofibromas. W. M. Craig and E. J. Steenrod.—p. 404.
- Paralysis of Inferior Oblique Muscle following Caldwell-Luc Operation. J. N. Novick.—p. 412.

Radiosensitivity of Malignant Neoplasms.—The author analysed the results obtained in a series of thirty-two successive cases of laryngeal carcinoma in which the only treatment was roentgen irradiation according to the principles of Coutard. Pieces of the tumours were sectioned and classified according to Broder's method. The authors conclude, contrary to accepted opinion, that for all practical purposes there are no pathological criteria which permit differentiation between radiosensitive and radioresistant laryngeal carcinomata if protracted fractional roentgen therapy has been used.

Haemorrhage into Maxillary Sinus.—Over a period of ten years the author has treated twelve patients with spontaneous maxillary sinus haemorrhage. Such cases are rare, and the only characteristic finding is evidence of active bleeding from the middle meatus on the involved side. The condition occurs as an occasional complication of hyperplastic maxillary sinusitis. In ten patients an external radical operation on the antrum was performed; in two the bleeding was controlled by antral lavage and did not recur.

British Journal of Ophthalmology

London vol. 22 October, 1938

- Hereditary Degeneration of Rat Retina. M. C. Bourne, D. A. Campbell, and K. Tansley.—p. 613.

Suppression of Vision in Squint.—Suppression does not always produce amblyopia; suppression only occurring when the other eye is fixing. Areas of suppression may be investigated by the colour test or the mirror-screen test. In normal correspondence the suppression is in the macular area, while in abnormal correspondence there is a larger area of suppression but not in the macular area. The grades of binocular vision enunciated by Worth are revised by the author. Simultaneous perception may develop normally or abnormally. If the former, it is succeeded by normal correspondence, true fusion, and stereoscopic vision. Abnormal development leads to abnormal correspondence.

Radon Seeds.—A new method of applying radon seeds to the sclera for the treatment of intraocular growths consists in stitching in the desired position a mould of dental stent containing the radon seeds.

- Nutrition of Promonic Acid Bacteria. H. G. Wood, A. A. Andersen, and C. H. Werkman.—p. 201.

Variation in Gonococci.—Serological typing of gonococci must take account of the fact that cultivation on artificial media causes a degenerative change with loss of type-specificity. Evidence is presented that gonococci also undergo this change in the body when the disease passes into its chronic stage.

Journal de Chirurgie et Annales de la Société Belge de Chirurgie

Brussels vol. 37 July-August, 1938

- Surgery of Lung (excluding Tuberculosis). O. Coquet and J. Govaerts.—p. 218.
- Regional Anaesthesia in Surgery of Lung. P. Santy.—p. 218.
- Result of Treatment of Abscess of Lung. P. Santy.—p. 220.
- Pulmonary Suppuration. de Fourmetraux.—p. 223.

- Sensitization and Antibody Formation with Increased Resistance to Tuberculous Infection induced by Heat-killed Tubercle Bacilli. J. Freund and E. L. Orin.—p. 273.

Neurone Degeneration in Vitamin Deficiency.—An attempt to produce a condition akin to pernicious anaemia in young pigs had an unexpected and hitherto unexplained result. The dietary deficiency employed was the substitution for yeast of thiamin (vitamin B₁) and riboflavin, and its effect was a selective degeneration of the peripheral sensory neurone causing severe ataxia. In spite of symptomatic resemblances this condition differs in its morbid anatomy from tabes, pellagra, and subacute combined degeneration of the cord. An attempt is now being made to determine whether deficiency of any component of the B₁ complex is responsible.

Heated Thermometer Anemometer.—A new form of anemometer is described by which air velocities of 10 to 6,000 feet a minute can be quickly and accurately determined. In principle the bulb of a thermometer is heated by a surrounding electric coil, the voltage being recorded, and the registered temperature is compared with that of a similar thermometer not so heated. By means of tables (or a given equation) from the difference in readings in conjunction with the voltage used the velocity can be determined. The instrument is recommended for measuring air movement in rooms or in front of exhaust hoods where other kinds of instruments are inconvenient or impossible.

Reflex Epilepsy. V. Pitha.—p. 178.

Tubular Meningitis.—The authors describe in detail the case of a young woman, aged 28, who showed symptoms of chronic meningitis over a period of five months. At necropsy the meninges showed a lymphocytic and plasma-cell infiltration with, in places, granulation tissue resembling that of a tuberculous reaction. This was associated with masses of round mycotic-like elements which were considered to belong to the torula group of mycotic parasites.

Relief of Paroxysmal Hypertension by Excision of Pheochromocytoma.—This article reviews eleven cases of paroxysmal hypertension due to retroperitoneal pheochromocytoma in which operative treatment was carried out successfully. Each case is described fully. An analysis is given of the adrenaline content of the tumours.

Congenital Anorchia.—Rea points out that congenital anorchia is a rare anomaly and that to date only twenty-nine unilateral and eleven bilateral cases have been reported. In this paper six cases of probable monorchia are presented, four left-sided and two right-sided. Three cases had an associated inguinal hernia, which was diagnosed before operation, and at operation all six cases had evidence of hernia.

Metabolism of Lipids in Cancer and in Gastric and Duodenal Ulceration and Influence of Resection of Stomach thereon (Ger.). K. Maruta and K. Inawasiro.—p. 175.

Complement-fixation Reaction of Pleural Effusions.—It is difficult to use this method for diagnosis, especially in effusions from patients in whom there are no other signs of tuberculosis. The results of the reaction in blood and effusion correspond in 76 to 88 per cent. of cases. When effusions became purulent the complement-fixation reaction usually became negative, in spite of the presence of tubercle bacilli; the presence of antibodies in an effusion prevents the growth of tubercle bacilli.

HORMONE TREATMENT

in imperfect descent of the testis

"The disadvantage of waiting for spontaneous descent in any except the retractile type is that if an anatomical abnormality be present, the diagnosis of which may deceive even the elect, spontaneous descent can never occur. Waiting until after puberty in the hope of spontaneous descent is in such a case an unnecessary and unjustifiable delay. Analysis of the results in the present series shows that if in cases of doubt a retained testis does not respond after six months of hormone treatment, it is highly probable that there is an anatomical abnormality."

"Vitamin B₁ deficiency an outstanding fault in the diet of many millions of people"

(B.M.J., 16 Oct., 1937, p. 753)

The reduction in Vitamin B₁ intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent., and may be as much as 70 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B acts as a limiting factor in the maintenance of health and nutrition, and often results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International Units, an amount sufficient to raise a deficient diet to an optimal level.

The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamin B₂ and B₆, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B₁ activity with no addition whatsoever. Clinical sample and literature on request. Vitamins Ltd., The Bemax Laboratories (Dept. B.73), 23, Upper Mall, Hammersmith, W.6.

Habitual Abortion and Dietary Sterility

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertitol.

Type all pneumonias—

PNEUMOCOCCUS TYPING

RAPID—ACCURATE

THE NEUFELD METHOD of type diagnosis has made specific serum therapy practicable.

Typing directly from sputum frequently permits a type diagnosis within a few minutes.

Early specific treatment—so vital to successful serum therapy—is possible only when the pneumococcus type is determined *early*.

Therapeutic sera are now available for a greater number of pneumococcus types. Approximately 75% of all adult pneumococcus pneumonias can be treated by means of specific sera for Types 1, 2, 4, 5, 7, and 8.

"Diagnostic Antipneumococcic Sera (Rabbit), *Lederle*" for typing by the Neufeld reaction, are available in the following packages:

—1.0 CC. VIAL 4s. 1d.

For each of the monovalent types and for the following combinations:—

Mixture "A"—containing Types 1, 2 and 7

Mixture "B"—containing Types 3, 4, 5, 6 and 8

Mixture "C"—containing Types 9, 12, 14, 15 and 17

Mixture "D"—containing Types 10, 11, 13, 20, 22 and 24

Mixture "E"—containing Types 16, 18, 19, 21 and 28

Mixture "F"—containing Types 23, 25, 27, 29, 31 and 32

FOR TYPES I TO XXXII

*Halibut Oil and orange
juice with a standardised
vitamin content*

Halycitrol is issued for the benefit of those difficult patients—children and fastidious invalids—whose condition calls for the administration of the Vitamins A and D, but who are unable to take halibut oil unless thoroughly disguised. But Halycitrol is more than just an elegant and delightfully flavoured product. In the finest medicinal glucose it contains a *standardised and guaranteed* quantity of Vitamins A and D in the form of Crookes' pure halibut oil, and Vitamin C, orange juice.

Each teaspoonful contains 2,600 International Units of Vitamin A, 220 International Units of Vitamin D₃ (natural Vitamin D), and 2 International Units of Vitamin C.

Ergoapiol - (Smith)

A Menstrual Regulator...

When the periods are irregular, due to constitutional causes, ERGOAPIOL (Smith) is a reliable prescription. Containing apiol (M.H.S. special) together with ergot, aloin and oil of savin of the highest quality, this preparation effectively stimulates uterine tone and controls menstrual and postpartum bleeding.

In cases of Amenorrhea, Dysmenorrhea, Menorrhagia and Metrorrhagia, Ergoapiol serves

as a good uterine tonic and hemostatic. Valuable in obstetrics after delivery of the child and for the menstrual irregularity of the Menopause.

Prescribe 1 to 2 capsules 3 or 4 times daily. Supplied only in packages of 20 capsules. Literature on request.

As a safeguard against imposition the letters MHS are embossed on the inner surface of each capsule, visible only when the capsule is cut in half as shown.

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of *TAXOL*, revert to normal and regular peristalsis.

The TERRY CEILING MODEL

Anglepoise

As good as a second right hand in the surgery

Yet another tremendous advance in surgery examination lamps—the Ceiling Model Terry Anglepoise. Out of the way, yet instantly to hand at a touch, pouring its strong, penetrating, concentrated beam *right on to the spot*, without any distracting glare in the user's eyes. Will practically reach to any part of the average surgery, thus avoiding awkward light-shifting when the patient must not be moved. Leaves both hands free. A perfect examining and dressing lamp. For sheer efficiency and convenience nothing can simply approach the **ANGLEPOISE**—adjustable to 1,001 positions at a finger touch—and poised at any angle. Simply marvellous for all "close" work as it throws the clear light necessary for extreme accuracy. It can be brought as close as required. Saves on light bills—a 25 watt bulb works like a 60! Scientifically built—every part superlatively made. Chromium-plated arms, tireless springs—for perfect balance. In several models. Models for fixing to wall or table, and on smooth-running castors. "A Triumph for Terry Springs." Prices from 50/- (U.K. only). Patented at Home and Abroad.

MINCHIN'S CHESTPIECES

(REGISTERED)

For Single and Binaural Stethoscopes.

Being set at right angles to those in general use afford the following advantages: Time is saved, as little undressing is necessary. Bed patients can be examined without disturbance. The heart can be examined whilst patient lies face down, with the result that sounds are much more distinct. This also applies to the Foetal Heart. Children can be more readily examined by this Chestpiece than by the older patterns as it is not necessary to stand in front of them. Now made in two sizes, 12in. and 14in. Also made in non-inflammable Tortoise-shell Celluloid.

To be obtained from all Surgical Instrument Makers.

THE MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.
Telephone: RODNEY 3841.

A CLINIC instituted by the London County Council for treatment of Nervous and Curable Mental Disorders. Voluntary patients only received. New Out-patients.—MEN: Mondays and Thursdays, 2 p.m. WOMEN: Tuesdays and Fridays, 10 a.m. 2 p.m. CHILDREN: Mondays and Fridays, 10 a.m. In-patients: (a) 235 beds (both sexes) in wards of separate rooms, including 35 beds in use as a King's College Hospital, which is in use as a temporary annexe of the Maudsley Hospital; (b) a special ward (including some private rooms) for those patients of each sex who are paying the full cost and are otherwise suitable. TERMS: £5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.

Terms include (with rare exceptions) all facilities of treatment, for which there are exceptional facilities, as there is a staff of Consultant Specialists and the Central Laboratory of London County Mental Hospitals is attached to the Maudsley. Inquiries of EDWARD MARSHALL, M.D., L.R.C.P., F.R.C.S., Medical Superintendent.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — WOODBRIDGE, SUFFOLK

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the
RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 216 (Toll Call from London).

Proprietors: The Norwood Sanatorium, Limited.

RUTHIN CASTLE, NORTH WALES

A Private Hospital or Clinic for the diagnosis and treatment of Internal Diseases (except Mental or Infectious Diseases). The Clinic is provided with a full staff of doctors, bacteriologists, chemists, radiologists, dietists, nurses, masseurs, and masseuses.

The surroundings are beautiful. The climate is mild. There is central heating throughout. The annual rainfall is 30.5 inches, that is, less than the average for England.

The inclusive weekly fees are from 15 guineas a week, according to the room occupied; rooms with bathroom are from 21 guineas. The charges include all chemical, bacteriological, X-ray or other examination advised by the doctors, and all the usual forms of treatment, in addition to board and lodging. There are no extra charges except for alcohol (when ordered) and laundry. An examination and consultation fee of 15 guineas is charged on the first visit.

Address: THE SECRETARY, Ruthin Castle, North Wales.

Telegrams: Castle, Ruthin. Telephone: Ruthin 66.

FOR THE TREATMENT OF MENTAL DISORDERS

Also completely detached villas for mild cases, with private suites if desired. Voluntary patients received. Twenty acres of grounds. Hard and Grass Tennis Courts, Putting Greens, Bowls, Croquet, Squash Rackets, Recreation Hall with Badminton Court, and all indoor amusements, including Wireless and other Concerts, Occupational Therapy, Callisthenics, and Dancing Classes, X-ray and Actino-therapy, Prolonged Immersion Baths, Operating Theatre, Pathological Laboratory, Dental Surgery, and Ophthalmic Dept. Chapel. Senior Physician, Dr. HUBERT JAMES NORMAN, assisted by three Medical Officers, also resident, and visiting Consultants. An Illustrated Prospectus giving fees, which are strictly moderate, may be obtained upon application to the Secretary.

The Convalescent Branch is HOVE VILLA, BRIGHTON, and is 200 feet above sea-level.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D., M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres. Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

CRICHTON ROYAL, DUMFRIES for NERVOUS AND MENTAL DISORDERS

Cases of alcoholism and drug addiction are admitted.

This Hospital has every facility for complete investigation and treatment of the above conditions.

The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy. There is a fully equipped Gymnasium and indoor Swimming Bath under qualified instructors. Facilities are provided for all indoor and outdoor recreation, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens, and a Cinema.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country, and include an extensive farm (T.T. herd), gardens and orchards.

Private rooms, suites or villas are available, and special nurses can be provided.

As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week; Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Sup: P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law. Tel.: Dumfries 1119.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

INCORPORATING THE ROSS INSTITUTE.

POSTS OVERSEAS FOR MEDICAL MEN

A register is kept in the School of medical men who are prepared to be considered for posts overseas, and the School is frequently asked to advise plantation and mining companies when such posts fall vacant.

The salaries offered are attractive; conditions of service are governed by standardised forms of contract; and many of the posts offer to medical men a most interesting field in which to practise their profession.

It is desirable that candidates for posts overseas should hold a diploma in tropical medicine and hygiene. The course provided by the London School for the Conjoint Board's Diploma lasts six months and the tuition fee is £40. The course may be taken from October to March or from January to June. There are generally more vacancies in the course commencing in January.

The Director of the Ross Institute is always glad to interview medical men who would like information regarding the possibilities of a career overseas if they will be good enough to make an appointment to call on him. Enquiries may be addressed to

The Director.

UNIVERSITY OF LONDON.

The Senate invite applications for the UNIVERSITY READERSHIP IN MEDICINE tenable at the BRITISH POSTGRADUATE MEDICAL SCHOOL. Initial salary £800 a year.

Applications (twelve copies) must be received not later than first post on December 14th, 1938, by the Academic Registrar, University of London, Senate House, W.C.1, from whom further particulars should be obtained.

UNIVERSITY OF LONDON.

The Senate invite applications for the UNIVERSITY CHAIR OF MEDICINE tenable at UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL. Salary £2,000 a year.

Applications (twelve copies) must be received not later than first post on January 16th, 1939, by the Academic Registrar, University of London, Senate House, W.C.1, from whom further particulars should be obtained.

GUY'S HOSPITAL DENTAL SCHOOL.

Applications are invited for the WHOLE-TIME POST OF DENTAL RESEARCH FELLOW, the appointment to begin as soon after January 1st, 1939, as possible. Preference will be given to a biochemist who is prepared to undertake work on dental diseases. The appointment will be for two years in the first instance with the possibility of reappointment. The stipend will be at the rate of £400 per annum.

Applications, accompanied by the names of three persons to whom reference may be made, should be submitted not later than December 31st, 1938, to the Dean, Guy's Hospital Medical School, S.E.1, from whom further particulars regarding the appointment may be obtained.

MIDDLESBROUGH EDUCATION COMMITTEE.

APPOINTMENT OF ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified men for a position as Assistant School Medical Officer in connexion with the medical inspection and treatment of school children, and such other duties as may be required by the Education Committee. The person appointed will be generally responsible to the School Medical Officer.

Commencing salary £500 per annum (provided the successful candidate has had not less than three years' postgraduate experience), rising by annual increments of £25 to £700 per annum. The Committee may at their discretion take into account previous experience as an Assistant School Medical Officer in determining the amount of the commencing salary. The successful candidate will be required to devote his whole time to the duties of the office. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass satisfactorily a medical examination. The appointment will be terminable by two calendar months' notice on either side.

Forms of application may be obtained on application to the Director of Education, Education Offices, Woodlands Road, Middlesbrough, to whom completed forms should be returned not later than Monday, December 12th, 1938.

Canvassing in any form will disqualify.
PRESTON KITCHEN.

Town Clerk's Office Town Clerk,
Municipal Buildings, Middlesbrough.
November 19th 1938.

COUNTY BOROUGH OF BOURNEMOUTH.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Male).

Applications for the above are invited from duly registered Medical Practitioners, who should be single and under 40 years of age and hold a Diploma of Public Health.

The person appointed may be required to undertake any public health work, but special experience of infectious diseases, including immunization, is desirable.

Board, lodging, and laundry will at present be provided at the hospital for infectious diseases, and for these a deduction of £100 per annum will be made from the salary, which will commence at £500 and rise by annual increments of £25 to a maximum of £700, less 5 per cent. deduction for superannuation purposes.

Application forms can be obtained from the Medical Officer of Health, Town Hall, Bournemouth, to whom they must be returned, with copies of three recent testimonials, not later than the first day of December 10th 1938.

Canvassing of any kind will be a disqualification.
Town Hall, HERBERT ASHLING,
Bournemouth Town Clerk.
November 18th. 1938.

BRITISH POSTGRADUATE MEDICAL SCHOOL.

There are three vacancies for HOUSE SURGEONS to the SURGICAL UNIT, B.M.A. Postgraduate Medical School, Hammer Lane, Hospital. The appointments are for six months and are not renewable. Salary £105 per week, with board, residence, and laundry. Dates to commence on January 1st, 1939.

Duties are mainly in General Surgery, but one appointment is to the Department of Trauma and Orthopaedic Surgery. Applicants must have held a previous House appointment.

Applications, with copies of testimonials, should be sent to the Dean, British Postgraduate Medical School, Duncane Road, Shepherd's Bush, London W.12, to arrive not later than the first post on Monday, December 12th 1938.

COUNTY COUNCIL OF DURHAM ASSISTANT WELFARE MEDICAL OFFICER

The County Health Committee invite applications for an Assistant Welfare Medical Officer (woman) at a commencing salary of £600 per annum, rising by annual increments of £25 to £700 per annum. Travelling allowance will be paid by the County Council in accordance with a scale to be approved from time to time.

The appointment will be held subject to three calendar months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered medical practitioner between the ages of 25 and 55 years, must devote the whole of her time to the duties of the office, and must not engage in private practice.

(2) She should either have had a previous appointment as Medical Officer of an ante-natal clinic, with the approval of the Minister of Health or have had at least three years' experience in the practice of her profession and special experience of practical midwifery and ante-natal work. The holding of a Diploma in Public Health will be deemed an additional qualification for the post.

(3) She will be subject to the directions of the County Medical Officer of Health.

(4) She will be required to reside in Durham City, or such other place as required by the Council.

(5) She must be prepared to undertake any duties in connection with the Maternity and Child Welfare Services of the County Council, including attendance at Birth Control Clinics.

(6) She must be prepared, if called upon, to act as locum tenens in other members of the medical staff in the County Medical Officer of Health.

(7) The appointment will terminate on marriage.
(8) The candidate appointed will be required to pass the County Council's medical examination and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, endorsed "Assistant Welfare Medical Officer," with copies of not more than three recent testimonials, must be addressed to the County Medical Officer of Health, Shire Hall, Durham, and must be received by him not later than Saturday, December 10th, 1938.

J. K. HOPE,
Shire Hall, Clerk of the County Council,
Durham.
November 21st, 1938.

COUNTY COUNCIL OF DURHAM DEPUTY COUNTY MEDICAL OFFICER OF HEALTH.

The County Health Committee invite applications for the appointment of a Deputy County Medical Officer of Health at a salary of £960 per annum. Reasonable travelling and out-of-pocket expenses will be paid by the County Council.

Applicants must be duly registered medical practitioners, holding a degree or diploma in Public Health, and the gentleman appointed will be required to devote the whole of his time to the duties of the office and to reside in the City of Durham or other approved centre. The appointment will be held subject to three calendar months' notice on either side.

He will be expected to undertake any duties required of him by the Council bearing on the public and medical services of the County, and will be under the administrative control of, and be responsible to, the County Medical Officer of Health for his duties.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of the Act, and the statutory contribution to the Superannuation Fund under that Act will be deducted from the salary.

Applications, marked "Deputy County Medical Officer of Health," together with copies of not more than three recent testimonials, must be sent to the County Medical Officer of Health, Shire Hall, Durham, not later than Saturday, December 10th, 1938.

J. K. HOPE,
Shire Hall, Clerk of the County Council,
Durham.
November 21st, 1938.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

During 1938 and 1939, the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa and Malaya.

QUALIFICATIONS.—Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY.—Initial salaries vary from £600 to £700, and rise by increments to a maximum of between £1,000 and £1,200.

PRIVATE PRACTICE.—Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS.—In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES.—Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.

TERMS OF APPOINTMENT.—The appointments are pensionable, subject to a probationary period which varies from two to three years.

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE.—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas.

DUTIES.—Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery, in public health, and in medical research.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S.W. 1.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry at the end of March, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list. Marriage Allowance is paid under the same conditions as for other Naval Officers.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1939.

COUNTY BOROUGH OF BRIGHTON. BRIGHTON MUNICIPAL HOSPITAL.

Applications are invited from duly qualified men for the post of **SECOND RESIDENT ASSISTANT MEDICAL OFFICER** at the Brighton Municipal Hospital.

Candidates must be single men, and preference will be given to those holding an F.R.C.S. or who produce evidence of having had practical surgical experience in a recognized hospital, as the appointment is primarily for surgical work, although not entirely so.

The appointment is for one year, but the person appointed will be eligible for appointment for a further year.

Salary £375 per annum, together with residential allowances valued for the purposes of superannuation at £150 per annum.

Forms of application, conditions of appointment, and list of duties may be obtained from the undersigned, which forms, duly completed and accompanied by copies of testimonials, must be returned to the Medical Superintendent not later than Wednesday, December 14th, 1938.

Canvassing the Committee, either personally or by letter, will be considered a disqualification for appointment.

S. J. FIRTH,

Medical Superintendent.

Brighton Municipal Hospital,

Elm Grove, Brighton 7.

November, 1938.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing for undermentioned position. Experience in resident appointment in general hospital for at least six months desirable. Married quarters not available. No accommodation for a woman.

COLINDALE HOSPITAL, The Hyde, Hendon, N.W.9.

Experience in the treatment of pulmonary tuberculosis essential.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division, County Hall, S.E.1, returnable by December 12th.

Canvassing disqualifies.

LONDON COUNTY COUNCIL.

ASSISTANT DISTRICT MEDICAL OFFICERS Required for Undermentioned Districts.

(1) AREA I, DISTRICT K (SOUTH POPLAR)—Provisional salary £350.

(2) AREA VIII, DISTRICT D (PART SOUTH-WARK)—Provisional salary £212 10s. (inclusive of payment for use of doctor's surgery for Council's patients).

(3) AREA X, DISTRICT G (WOOLWICH, NORTH OF RIVER)—Provisional salary £75 (inclusive of payment for use of doctor's surgery for Council's patients).

Persons appointed required to reside in or near districts.

Application form, with further particulars, obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division 2 (A), County Hall, S.E.1.

Canvassing disqualifies.

LONDON COUNTY COUNCIL.

CONSULTANT AND SPECIALIST SERVICES.

PART-TIME OBSTETRICIAN AND GYNAECOLOGIST (one position) required for duty at HACKNEY HOSPITAL and ST. LEONARD'S HOSPITAL, Shoreditch. Salary £800.

Officer responsible, subject to administrative control of Medical Superintendents, for obstetric and gynaecological work at these hospitals. Required to live within reasonable distance of hospitals, to visit them daily and as required.

Application forms (stamped addressed foolscap envelope necessary) from Medical Officer of Health (S.D.6), County Hall, Westminster Bridge, S.E.1, returnable by December 19th. Women eligible. Canvassing disqualifies.

CITY OF BRADFORD.

CITY SANATORIUM—GRASSINGTON.

ASSISTANT MEDICAL OFFICER required for a period of one year.

Salary £175 per annum, plus board-residence.

Form of application may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to the undersigned not later than December 12th, 1938.

N. L. FLEMING, Town Clerk.

Town Hall, Bradford

November 25th, 1938.

AMENDED ADVERTISEMENT. METROPOLITAN BOROUGH OF GREENWICH.

JUNIOR ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

The Council of the Metropolitan Borough of Greenwich is prepared to receive applications from registered Medical Practitioners for the appointment of Junior Assistant Maternity and Child Welfare Medical Officer in the Borough of Greenwich.

Applicants must not be more than 45 years of age, must have had experience in connexion with Maternity and Child Welfare work generally, must be Registered Medical Practitioners who, prior to April 1st, 1930, had held the appointment of Medical Officer of an Ante-natal Clinic with the approval of the Minister of Health, or who, subsequent to qualification, have had at least three years' experience in the practice of their profession and special experience of practical midwifery and ante-natal work. The possession of the Diploma in Public Health and resident obstetric experience will be considered additional qualifications. The person to be appointed will act generally under the direction and supervision of the Medical Officer of Health, who is the Administrative Medical Officer of the Maternity and Child Welfare Services.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum, but in the event of the successful candidate possessing the Diploma in Public Health the commencing salary will be increased to £550 per annum.

The successful candidate will be required to reside in the neighbourhood of the Borough Council's Maternity Home, to devote the whole of his or her time to the service of the Council, and not to engage in private practice.

The appointment will be subject to the provisions of the Council's Superannuation Scheme and will be terminable by three months' notice in writing on either side.

Applications must be made on forms, to be obtained from the undersigned, stating age, qualifications, and experience, and accompanied by copies of not more than three recent testimonials, must be sealed up and endorsed "Junior Assistant Maternity Medical Officer," and reach me not later than 12 o'clock noon on Monday, December 19th, 1938.

Canvassing members of the Council, either directly or indirectly, will be a disqualification.

Town Hall, Greenwich, S.E.10.

December 2nd, 1938.

D. J. REASON, Town Clerk.

SURREY COUNTY COUNCIL.

BOTLEYS PARK COLONY

(Certified Institution for Mental Defectives), near Chertsey, Surrey.

APPOINTMENT OF FIRST ASSISTANT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (male) for the whole-time appointment of Resident First Assistant Medical Officer at the above-mentioned Institution.

Commencing salary £400, rising by annual increments of £25 to a maximum of £500 per annum, with £50 extra if in possession of a degree or diploma in Psychological Medicine. In addition, emoluments of board, lodging, etc., will be provided, valued for superannuation purposes at £150 per annum. Should the successful candidate be married, he will receive the value of the emoluments in cash and be provided with a house on the estate, for which a rental of £45 per annum will be charged.

The appointment will be subject to the provisions of the Asylums and Certified Institutions (Officers' Pensions) Act, 1918, and to the Council's Staffing Regulations. The person appointed will be required to undergo a medical examination.

Applications, on forms to be obtained from the Medical Superintendent, Botleys Park, Chertsey, must be completed and returned to the Medical Superintendent not later than December 17th next.

DUDELEY AUKLAND,

November 22nd, 1938. Clerk of the Council.

BOROUGH OF HOVE.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered medical practitioners under the age of 40 for the above whole-time appointment. The duties will be of a general nature but special experience is necessary in Maternity and Child Welfare and Infectious Diseases, and applicants should possess the Diploma of Public Health.

The salary will be £500 per annum, rising by annual increments of £25 to £700 per annum, together with a car allowance of £50 per annum. The successful candidate will be required to pass a medical examination and to contribute to the Superannuation Fund.

Applications on the prescribed form, in be obtained from the undersigned, together with copies of three recent testimonials, must be received not later than Monday, December 19th, 1938.

Town Hall, W. JERMYN HARRISON,

Hove, November, 1938.

Town Clerk.

CITY OF LEEDS PUBLIC HEALTH DEPARTMENT.

ST. JAMES'S HOSPITAL.
(1,330 Beds.)

RESIDENT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (male) for the post of Resident Medical Officer at the St. James's Hospital, Leeds. Applicants must have had previous resident experience in a General Hospital.

Under the present scale of salaries of the Corporation the commencing salary for the post is £350 per annum, and the maximum £450 per annum, with annual increments of £25, subject to satisfactory service. The first increment will take effect on April 1st following the completion of twelve months' service. Board, residence, and laundry are provided, these emoluments being valued for superannuation purposes at £120 per annum.

The person appointed will be required to pass a medical examination and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922.

The appointment will be terminable by six months' notice.

Applications, on a form to be obtained from the undersigned, together with copies of three recent testimonials, and endorsed "Resident Medical Officer," must be received at the Public Health Department, 12, Market Buildings, Vicar Lane, Leeds 1, not later than 10 a.m. on Wednesday, December 14th, 1938.

Canvassing in any form, either directly or indirectly, will be considered a disqualification.

J. JOHNSTONE JERVIS,
Medical Officer of Health

BUCKINGHAMSHIRE COUNTY COUNCIL.

TWO ASSISTANT COUNTY MEDICAL OFFICERS OF HEALTH.

Applications are invited from registered Medical Practitioners, not over forty years of age, holding a registrable qualification in Public Health, Sanitary Science, or State Medicine, to act as Assistant County Medical Officer of Health and Assistant School Medical Officer of Health.

The duties will pertain mainly to School Medical Inspection and Maternity and Child Welfare work, but there will be opportunities for the investigation of sanitary conditions generally.

The salary is £600 per annum, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £700 per annum.

The successful applicants will be required to pay contributions under the Local Government and Other Officers' Superannuation Act, 1922, and to pass a medical examination as to physical fitness, the final appointment being subject thereto.

Particulars and conditions of application, which can be set out on the form of application, which can be obtained from the undersigned.

Application, on the prescribed form, accompanied by copies of not more than three recent testimonials, which will not be returned, should be addressed to the Clerk of the Bucks County Council, and delivered at the County Hall, Aylesbury, not later than 11 a.m. on Saturday, December 17th, 1938, marked "Assistant Medical Officer."

County Hall, Aylesbury, GUY R. CROUCH,
November, 1938. Clerk of the Bucks County Council

BOROUGH OF WIMBLEDON.

DEPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER.

Applications are invited for the above appointment from qualified and registered medical practitioners under 35 years of age, having at least three years' experience since qualification in Public Health work is necessary.

The Officer appointed will be required to reside in the Borough, to devote his whole time to the official duties, and to work under the direction of the Council's Medical Officer of Health.

The commencing salary is £650, rising by annual increments of £25 to a maximum of £750 per annum. The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the passing of a medical examination.

Application forms can be obtained from the Medical Officer of Health, Town Hall, Wimbledon, to whom they must be returned, with copies of three recent testimonials, not later than 10 a.m. on Monday, December 19th, 1938.

HERBERT EMERSON SMITH, T.L.B.,
Town Hall, Wimbledon, S.W.19
November 29th, 1938.

Appointments for Medical Officers in the ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force. Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry.

The period of service is 3 years—extendible to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study. Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission up to twelve months is allowed for appointments held at approved hospitals.

*Fuller information can be obtained from The Director
of Medical Services, Air Ministry, Kingsway, London.*

LEICESTERSHIRE COUNTY COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND DISTRICT MEDICAL OFFICER OF HEALTH.

Applications are invited for the joint whole-time appointment of an Assistant County Medical Officer of Health for the Administrative County of Leicester and Medical Officer of Health for the Rural District of Barrow-upon-Sear in the said County at a salary of £800 per annum, with a travelling allowance of £140 per annum. Office accommodation and clerical assistance will be provided by arrangements to be agreed upon by the appointing Authorities. The estimated total population of the Sanitary District is 38,340, the acreage of the area being 54,604.

Applicants, who should not be over forty-five years of age, must be duly qualified and registered male medical practitioners with experience in Public Health duties and must hold the Diploma in Public Health or its equivalent. The Officer appointed will be required to reside at such place in or adjacent to the Sanitary District as shall be approved. As regards the duties of an Assistant County Medical Officer of Health the Officer will act under the general control of the County Medical Officer of Health and will be required to perform such duties as may from time to time be prescribed. As regards his duties as District Medical Officer of Health the Officer will be subject to the sole control and direction of the Local Sanitary Authority.

The joint appointment is subject to the approval of the Minister of Health and the Board of Education and also, so far as the Office of District Medical Officer is concerned, to the provisions of the Sanitary Officers (Outside London) Regulations, 1935. The joint appointment will be one under the Local Government Superannuation Act, 1937, and the selected candidate will be required to pass a medical examination. The joint appointment will be determinable by three months' written notice on either side, subject so far as the office of the District Medical Officer of Health is concerned to the consent of the Minister of Health.

Forms of application, together with a list of duties, may be obtained from the undersigned and, accompanied by copies of not more than three recent testimonials, should be returned to him not later than December 13th, 1938.

Canvassing, directly or indirectly, will be deemed a disqualification.
County Offices, LUCAS E. RUMSEY,
Grey Friars, Clerk of the County Council,
Leicester, November 21st, 1938.

COUNTY BOROUGH OF TYNEMOUTH

ASSISTANT MEDICAL OFFICER (Female).

MATERNITY AND CHILD WELFARE.

Applications are invited from duly qualified and registered female Medical Practitioners under 40 years of age for the post of Assistant Medical Officer in the County Borough of Tynemouth Public Health Department. The duties will be in connection with the Maternity and Child Welfare Scheme. Candidates should possess a Diploma in Public Health, and preference will be given to those having special experience in the conduct of ante-natal and venereal diseases clinics.

The salary will be £500 per annum, rising by annual increments of £25 to a maximum of £760. The officer appointed will be required to devote her whole time to the duties of the post, particulars of which, together with forms of application, may be obtained from the undersigned.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1932, and the successful candidate will be required to pass a medical examination.

Applications, together with copies of three recent testimonials, must reach the undersigned not later than 10 a.m. on December 9th, 1938.

Canvassing, either directly or indirectly, will be a disqualification.
Town Clerk's Office, FRED G. EGNER,
14, Northumberland Square, Town Clerk.
North Shields
November, 1938.

AYR COUNTY COUNCIL.

HAEMATOLOGICAL TECHNICIAN.

Applications are invited from experienced LABORATORY TECHNICIANS for the above post. The person appointed will be required to work under the County Obstetrician, and the duties will consist in routine haemoglobin investigations and blood counts as required upon all patients attending the County Ante-natal Clinics and Maternity Hospitals. Salary will be at the rate of £240 per annum subject to deduction for superannuation.

Applications, stating age, sex, experience, and present appointment, along with copies of three recent testimonials, to be submitted to the Medical Officer of Health County Buildings, Ayr, before December 15th, 1938.

COUNTY BOROUGH OF SOUTH SHIELDS.

ASSISTANT SCHOOL MEDICAL OFFICER (JUNIOR)

Applications are invited from fully qualified and registered medical women for the post of Assistant School Medical Officer, at a salary of £500 per annum, rising by annual increments of £25 to £700 per annum.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1932, and the successful candidate will be required to pass a medical examination.

The person appointed will be under the administrative control of the Medical Officer of Health, and she must devote her whole time to the duties of the post and must not engage in private practice.

Forms of application may be obtained from the Medical Officer of Health, Stanhope Road, South Shields.

Applications, with copies of three recent testimonials, should be received at my office not later than 5 p.m. on December 14th, 1938, marked "Appointment of Assistant School Medical Officer".

Education Department, V. C. CARTER,
Town Hall, South Shields. Secretary.

COUNTY BOROUGH OF DERBY.

DERBY CITY HOSPITAL.

ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the post of Assistant Resident Medical Officer (male) at the above Hospital of 300 beds. This Hospital provides treatment for acute medical and surgical cases, obstetrics and children's diseases, etc.

Candidates must be registered in medicine and surgery.

The appointment is for a period of six months; two months' notice of termination of duties may be given on either side. The successful applicant will be required to commence duties on January 1st, 1939.

Salary at the rate of £200 per annum, with board and residence.

Applications, stating age, experience, and accompanied by three recent testimonials, should be sent to the undersigned as soon as possible.

GORDON LILICO,
Medical Officer of Health.
Public Health Department,
1, Derwent Street, Derby.

BOROUGH OF HESTON AND ISLEWORTH.**Appointment of
ASSISTANT MEDICAL OFFICER OF HEALTH
AND SCHOOL MEDICAL OFFICER.**

Applications are invited from duly qualified medical men with a Public Health qualification for the position of Assistant Medical Officer of Health and School Medical Officer.

Candidates will be required to carry out medical inspection of school children, bacteriological work, child welfare work, administer dental anaesthetics, and perform such other duties as may be allotted by the Medical Officer of Health.

The person appointed will be required to devote his whole time to the duties, to reside in the Borough, and will not be allowed to engage in private practice. The salary will be at the rate of £500 per annum, rising to £700 per annum by annual increments of £25.

A deduction of 5 per cent will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the appointment will be subject to medical examination.

Copies of the application form and terms of appointment can be obtained from the Medical Officer of Health, 92, Bath Road, Hounslow.

Applications, accompanied by copies of not more than three recent testimonials, enclosed in a sealed envelope endorsed "Assistant Medical Officer," must be delivered to the undersigned not later than noon on Friday, December 16th, 1938.

Council House, Hounslow. HAROLD SWANN, Town Clerk.

**BOROUGH OF EALING.
ASSISTANT MEDICAL OFFICER OF HEALTH.**

Applications are invited from duly qualified medical men with a Public Health qualification for the position of Assistant Medical Officer of Health.

A candidate must have had at least three years' experience in the practice of his profession. The person appointed will be required to carry out medical inspection of school children and child welfare work and perform such other duties as may be allotted as Assistant to the Medical Officer of Health and School Medical Officer.

He will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. The salary will be at the rate of £600 per annum, rising by £25 per annum to £700.

A deduction of 5 per cent will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application forms and terms of appointment can be obtained from Dr. THOMAS ORR, Medical Officer of Health, Town Hall, Ealing, W.5, to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than December 15th.

Town Hall, Ealing, W.5. R. H. WANKLYN, Town Clerk.

BOROUGH OF BERMONDSEY.

Applications are invited from fully qualified and registered Medical Practitioners (Women—Widows or Single) for the position of ASSISTANT MEDICAL OFFICER for Maternity and Child Welfare.

The salary will be at the rate of £600 per annum, rising by two annual increments of £50 to £700 per annum and be subject to deductions under the Council's Superannuation Acts. The person appointed will be required to pass satisfactorily a medical examination. Candidates must not have reached their 35th birthday on the date of their application. Preference will be given to applicants having special experience in the care of women and children. The person appointed will be required as a routine duty to give lectures on hygiene to audiences both of school children and of adults, and to devote the whole of her time to the work of the Council. Further particulars of the duties can be had on application to the Medical Officer of Health.

Applications on forms to be obtained from the undersigned and accompanied by copies of not more than three recent testimonials, must be delivered not later than December 16th, 1938.

Municipal Office, Spa Road, Bermondsey, S.E. 16. FRANCIS J. R. MOUNTAIN, Town Clerk.
December 2nd, 1938.

**SOUTH LONDON HOSPITAL FOR WOMEN,
Clapham Common, S.W.4.**

Applications are invited from medical women as CLINICAL ASSISTANT FOR GYNAECOLOGICAL OUT-PATIENTS, to attend on Monday afternoons. Applications, with testimonials, to be sent to the Secretary at the Hospital.

BOROUGH OF EALING.**ASSISTANT MEDICAL OFFICER.**

Applications are invited from duly qualified medical men (single) with a Public Health qualification for the position of Assistant Medical Officer.

A candidate must have had experience in the treatment of cases of infectious disease at an Isolation Hospital. The duties will include the medical care of patients in the Ealing and Brentford and Chiswick Isolation Hospital, South Ealing, and the medical inspection and treatment of school children at schools and health centres in the Borough of Ealing.

The person appointed will reside at the Isolation Hospital, where furnished rooms and board will be provided.

He will be required to devote his whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £450 per annum, rising by £25 per annum to a maximum of £550, plus board and residence, as indicated above and valued at £150 per annum.

A deduction of 5 per cent will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application forms and terms of appointment can be obtained from Dr. THOMAS ORR, Medical Officer of Health, Town Hall, Ealing, W.5, to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than December 15th.

Town Hall, Ealing, W.5. R. H. WANKLYN, Town Clerk.

Applications on the prescribed form, with copies of three testimonials to be returned to the Secretary by December 10th.

EAST HAM MEMORIAL HOSPITAL, Shrewsbury Road, E.7. (104 Beds.)

Applications are invited for the post of HOUSE SURGEON AND CASUALTY OFFICER (male) for six months commencing January 1st. Salary at the rate of £120 per annum, with board, residence and laundry.

Applications, stating age, nationality, experience, and full particulars, together with copies of three recent testimonials, should reach the undersigned by December 14th.

REGINALD PERRY, Secretary.

NATIONAL HOSPITAL, QUEEN SQUARE, W.C.1.

RESEARCH FELLOWSHIP.

By the generosity of a private donor a FULL-TIME RESEARCH FELLOWSHIP has been created for the investigation of DISORDERS OF MUSCLE at the National Hospital, Queen Square, London, W.C.

The Fellowship will be open to graduates in science or medicine and is of the value of £500 per annum, tenable for one year in the first instance.

Applicants should state their previous experience and the method of investigations they propose to adopt.

Further particulars may be obtained from the Secretary, National Hospital, Queen Square, W.C.1, and applications should reach him by January 15th, 1939.

ROYAL MASONIC HOSPITAL, Ravenscourt Park, W.6.

A post of RESIDENT MEDICAL OFFICER (male), preferably with M.R.C.P. qualification, will be vacant on January 1st, 1939. Salary at the rate of £300 per annum, with board, residence, and laundry. The appointment is for twelve months. Candidates must be registered, and must have held resident appointments in General Hospitals.

The Institution (145 beds at present, but to be increased) is primarily for paying patients of both sexes of moderate means usually unable to afford ordinary Nursing Home treatment, etc.

Applications, stating full particulars, to be sent on or before Monday, December 5th, 1938, to the Honorary Secretaries, from whom further information may be obtained.

HOSPITAL FOR TROPICAL DISEASES.

RESIDENT MEDICAL SUPERINTENDENT.

The Committee of Management of the Seamen's Hospital Society invite applications for this post, falling vacant on January 1st, 1939. The appointment will be tenable for two years. Minimum commencing salary £250 p.a., with board, residence and laundry. Candidates must be male, single, and legally qualified and registered. Membership of the Royal College of Physicians and some knowledge of tropical medicine is desirable, but not essential.

Applications, stating age, with copies of not more than three recent testimonials, to be sent on or before December 7th, 1938, to

D. A. C. PRICE,
Hospital for Tropical Diseases, Secretary,
25, Gordon Street, W.C.1.

HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars.

The Committee of Management will shortly appoint an additional member of the HONORARY STAFF. Candidates should be either Members of the Royal College of Physicians (London) or Fellows of the Royal College of Surgeons (England).

Applications, with testimonials in support, must be sent before December 12th to L. Mundy, Secretary to the Hospital for Diseases of the Skin, 71, Blackfriars Road, S.E.1, from whom any further information may be obtained.

VIOLET MELCHETT INFANT WELFARE CENTRE.

Flood Walk, Chelsea, S.W.3.

Applications are invited for the position of MEDICAL OFFICER in charge of WEEKLY ANTE-NATAL and POST-NATAL CLINIC. Wednesdays, 2 to 4 p.m.; £11s. 6d. per session. Good experience essential.

Applications, with full particulars and three testimonials, should be sent to the Hon. Secretary by December 9th, 1938.

KING'S COLLEGE HOSPITAL.

The Committee of Management invite applications for the post of ASSISTANT PHYSICIAN.

Applications, with copies of three testimonials, should be sent before December 10th to the House Governor, King's College Hospital, Denmark Hill, S.E.5, from whom particulars of the duties may be obtained. Candidates must be Members or Fellows of the Royal College of Physicians of London.

ST. JOHN'S HOSPITAL, LEWISHAM, S.E.13.

Applications are invited for the resident appointment of HOUSE SURGEON (male) tenable for six months from January 1st, 1939, at a remuneration of £100 p.a. Applications, with copies of testimonials, should be received by the undersigned not later than Tuesday, December 13th.

J. C. GILBERT,
Secretary-Superintendent

THE HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.1.

A vacancy exists for a MORBID ANATOMIST AND SEBAG-MONTEFIORE RESEARCH FELLOW.

The appointment is whole-time and is resident.

The appointment in the first place is for one year, but is renewable. Initial salary according to experience, but not less than £600 per annum.

The successful candidate will be required to take up his duties in March, 1939, or subsequently by arrangement.

Candidates must be registered Medical Practitioners and trained in Pathological Anatomy and Histology.

Applications, accompanied by copies of not more than three testimonials given specially for the purpose, must be delivered to the undersigned not later than Monday, January 30th, 1939.

Candidates must be prepared to appear before the Joint Committee at their meeting on Wednesday, February 1st, 1939, at 4.45 p.m.

Forms of application and details of the appointment will be supplied on application.

HERBERT F. RUTHERFORD,
November, 1938. Secretary

THE HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.1.

The post of CLINICAL PATHOLOGIST will be shortly vacant. Salary £750 per annum.

The appointment is whole-time and non-resident. Facilities, within certain limits, will be given to private pathological practice.

The successful candidate will be required to take up his duties preferably on March 1st, 1939.

Candidates must be registered Medical Practitioners with special experience in bacteriology and clinical pathology.

Applications, accompanied by not more than three testimonials given specially for the purpose, must be delivered to the undersigned not later than noon on Monday, December 19th, 1938.

Candidates must be prepared to appear before the Joint Committee on Wednesday, December 21st, 1938, at 4.45 p.m.

Forms of application and details of the appointment are obtainable from the undersigned.

HERBERT F. RUTHERFORD,
November, 1938. Secretary

ST. PETER'S HOSPITAL FOR STONE ETC., Henrietta Street, Covent Garden, W.C.2.

The appointment of CLINICAL ASSISTANTS to the undermentioned members of the Honorary Staff, who attend the Out-patients' Department at the times indicated, will be considered at an early date. A fee of five guineas becomes payable to the funds of this Hospital on appointment, and applications should reach the undersigned on or about Tuesday, December 6th.

SALE OF LAND.

CITY OF LIVERPOOL.

HOUSING ACT, 1936.

Site for Doctor's and Dentist's Residences, Woolfall Heath Estate, Knowsley.

The Housing Committee of the Liverpool Corporation are prepared to consider TENDERS for the purchase of two sites, each containing about 800 square yards, situated in close proximity to the proposed shopping centre, on the Woolfall Heath Estate, Knowsley.

The site will be sold on a lease of 999 years, and, if required, the purchase monies may be commuted into annual ground rents.

Particulars can be obtained at the office of the Director of Housing, Blackburn Chambers, Dale Street, Kingsway, Liverpool, 2, where a plan showing the sites is available for inspection.

Tenders should be delivered through the post at the office of the Town Clerk, Municipal Buildings, Dale Street, Liverpool, 2, on or before 12 o'clock noon on Monday, December 12th, 1938, the envelope to be endorsed "Tender, Doctor's/Dentist's Site, Woolfall Heath Estate."

Municipal Buildings, W. H. BAINES,
Liverpool, November, 1938. Town Clerk.

APPOINTMENTS.—Contd.

PRINCE OF WALES HOSPITAL, PLYMOUTH.

Incorporating South Devon and East Cornwall Hospital, Greenbank Road; Royal Albert Hospital, Devonport; Central Hospital, Lockyer Street.

Applications are invited for the post of HONORARY ASSISTANT SURGEON to the Hospital (the Honorary Surgical Registrar is a candidate for the post).

Candidates must be Masters of Surgery at a University of the United Kingdom or Fellows of the Royal College of Surgeons of England or of Edinburgh.

Applications and testimonials must reach the undersigned, from whom the rules and regulations governing the appointment may be obtained, on or before December 24th, 1938.

Personal canvassing disqualifies, but candidates may send copies of their application and testimonials to the members of the Board.

ARTHUR R. CASH,
General Superintendent.

November 30th, 1938.

ROYAL BUCKINGHAMSHIRE HOSPITAL, Aylesbury. (112 Beds.)

Applications are invited for the posts of SENIOR and JUNIOR RESIDENT MEDICAL OFFICERS (male) for six months beginning January 1st, 1939. Salaries £200 and £150 p.a. respectively, with full board, residence in own flat, and laundry.

Previous Hospital experience is desirable. Opportunity will be afforded to undertake all branches of medical and surgical practice, including anaesthesia, and to work with London consultants.

Selected candidates will be required to attend for interview by the Medical Committee on Friday, December 16th, 1938.

Applications must reach the undersigned by Monday, December 12th, 1938.

F. G. DAWES, Secretary.

WORTHING HOSPITAL.

Applications are invited for the post of SURGEON to the Hospital. Candidates must be Fellows of the Royal College of Surgeons of England or Masters in Surgery of a British university. They should not be engaged in general practice and must reside within easy access to the Hospital.

Applications, with not more than three testimonials (copies only), together with the names of persons to whom reference can be made, should be sent to the Secretary-Superintendent of the Hospital, from whom further particulars may be obtained. They should be received not later than December 17th, 1938.

THE QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, London, E.2. (160 Beds.)

HOUSE PHYSICIAN required January 1st, 1939. CASUALTY OFFICER required January 1st, 1939. Some Dermatological work in addition.

Six months appointment. Salary at the rate of £100 per year, with board, lodging, and laundry in kind.

Applications must be made on forms to be obtained from the undersigned, and be sent in, with copies of not more than three testimonials, on or before December 7th, 1938.

CHARLES H. BESSELL,
November 14th, 1938. Secretary.

THE GENERAL INFIRMARY AT LEEDS. (673 Beds.)

Applications are invited for the post of FULL-TIME ASSISTANT in the new X-RAY DIAGNOSTIC DEPARTMENT.

The commencing salary will be at the rate of £400 p.a., and the Federated Superannuation Scheme for Nurses and Hospital Officers will apply.

Candidates must be duly registered Medical Practitioners, with special experience in Radiological work, and should possess a Radiological Diploma.

Applications, accompanied by copies of recent testimonials, stating age, qualifications, etc., should be sent to the undersigned not later than December 9th, 1938.

S. CLAYTON FRYERS,
House Governor and Secretary.

THE ROYAL HOSPITAL, WOLVERHAMPTON (Incorporated under Charter).

Applications are invited for the post of REGISTRAR to the FRACTURE and ORTHOPAEDIC DEPARTMENT.

The Hospital contains 300 beds and is recognized by the various Examining Bodies for a part of the requisite attendance on Medical and Surgical Practice.

Candidates must possess one of the higher qualifications in Surgery.

The post is a non-resident one, and the appointment will be, in the first place, for twelve months. Salary £400 per annum.

Applications, with copies of testimonials, to be forwarded to the undersigned, from whom further information may be obtained.

W. H. HARPER,
November 22nd, 1938. House Governor.

THE WEST NORFOLK AND KING'S LYNN GENERAL HOSPITAL. (112 Beds.)

RESIDENT SURGICAL OFFICER.

Applications are invited for the above post, which will become vacant on January 9th, 1939. Salary £300 per annum.

The duties include much operative work, and preference will be given to a candidate holding the F.R.C.S. Eng. diploma.

Applications, stating nationality, age, together with copies of recent testimonials, should be sent to the undersigned.

JOSEPH E. SEARJEANT, F.R.C.S.,
House Governor and Secretary.

THE PRINCESS BEATRICE HOSPITAL, Earl's Court, London, S.W.5. General Hospital (81 Beds.)

RESIDENT SURGICAL OFFICER (male) required for a period of six months in the first place from January 1st, 1939, eligible for re-election. Salary at the rate of £200 per annum, with board, residence, and laundry (together with £25 to cover all duties during the six months relating to private patients). Previous resident experience and F.R.C.S. essential.

Applications, with copies of three recent testimonials, should be received by the Secretary not later than 9 a.m., Monday, December 5th, 1938.

THE PRINCESS BEATRICE HOSPITAL, Earl's Court, London, S.W.5. General Hospital (81 Beds.)

Applications are invited for the appointment of HONORARY ASSISTANT SURGEON to the Ophthalmic Department of The Princess Beatrice Hospital. Candidates must be F.R.C.S. Eng. and engaged in consulting practice only.

Applications, together with copies of three recent testimonials, should be received by the Secretary by the first post on December 5th, 1938.

YORK COUNTY HOSPITAL. (204 Beds.)

Applications are invited for the post of HOUSE SURGEON for a period of not less than six months. Salary £150 per annum, with board, residence and laundry.

Applications, stating age and previous experience, together with copies of not more than three recent testimonials, to be sent to the undersigned not later than 9 a.m. on Monday, December 5th, 1938.

J. R. MACKRILL, Secretary.

MAIDENHEAD HOSPITAL, BERKSHIRE. (56 Beds.)

Applications are invited for the posts of HON. GYNAECOLOGIST and HON. DERMATOLOGIST respectively.

Applications, with copies of recent testimonials, should be received by the undersigned by December 17th, 1938.

R. J. FANNING,
Superintendent-Secretary.

WEST LONDON HOSPITAL, Hammersmith, W.6. (219 Beds.)

Required, ONE HOUSE PHYSICIAN and THREE HOUSE SURGEONS (males). These appointments are tenable for six months from January 1st next, subject to one month's notice on either side. The duties of the House Physician include some work in the Neurological and Dermatological Departments. The duties of one House Surgeon include some work in the X-ray Therapy Department, another some work in the Gynaecological Department, and the third some work in the Ear, Nose and Throat and Ophthalmic Departments. For this last appointment it would be desirable that candidates should be reading for the D.L.O. Salary at the rate of £100 a year, with full board and lodgings.

Candidates must be registered under the Medical Act.

Applications (which must be on printed forms obtained from me) must reach me not later than first post on Thursday, December 15th. Selected candidates will be required to call upon each member of the Medical Staff as directed; to be in attendance at a Meeting of the Medical Council at 4.30 p.m. on Friday, December 23rd, and at the House Committee Meeting at 5 p.m. the same day, when the appointments will be made.

H. A. MADGE,

Secretary.

WOOLWICH AND DISTRICT WAR MEMORIAL HOSPITAL, Shooters Hill, London, S.E.18. General Hospital (112 Beds.)

The Board of Management invites applications from suitably qualified male candidates for appointment as CASUALTY OFFICER for six months from January 1st, 1939. The remuneration will be at the rate of £100 per annum, plus board, residence, and laundry. The candidate appointed will act as deputy for the Resident Surgical Officer, with consequent opportunities for major surgery.

The closing date for the receipt of applications (which should be made on the prescribed form obtainable from the undersigned) is Monday, December 12th, 1938, and short-listed candidates will be invited to meet the Appointments Committee (at the Hospital) on Thursday, December 15th, at 4.45 p.m.

R. S. G. HUTCHINGS,

Secretary.

WEST HAM HOSPITAL FOR NERVOUS AND MENTAL DISORDERS, Goodmayes, Ilford, Essex.

Applications are invited for a Male JUNIOR ASSISTANT MEDICAL OFFICER at the above Hospital. Candidates must be unmarried.

The commencing salary is at the rate of £350 p.a. annum, rising by annual increments of £25 to a maximum of £450 per annum, together with emoluments consisting of board, laundry, and attendance. The value for superannuation purposes at £150. The person appointed will also be paid, in addition to his salary, the sum of £50 p.a. per annum on obtaining the Diploma of Psychological Medicine.

The appointment is subject to the provisions of the Asylum Officers' Superannuation Act, 1909, Class 1, and to a satisfactory medical examination.

The Hospital is situated ten miles from London and experience. Applications, stating age and experience, accompanied by copies of three recent testimonials, must reach the Medical Superintendent not later than December 12th, 1938.

THE WILLESDEN GENERAL HOSPITAL, Harlesden Road, N.W.10.

OUT-PATIENT DEPARTMENT CLINICAL ASSISTANTS (HONORARY).

Applications are invited for appointment to the following sessions:—

GYNAECOLOGICAL—Thursday mornings

SURGICAL—Friday afternoons

MEDICAL—Friday mornings

Applications should be forwarded to the Secretary, from whom further details of the appointments may be obtained, and should be received not later than first post on Tuesday, December 13th, 1938.

November 28th, 1938.

THE WILLESDEN GENERAL HOSPITAL, Harlesden Road, N.W.10.

Applications are invited from fully-qualified and registered candidates (unmarried) for the appointment of a Resident Officer, to hold the appointment of CASUALTY OFFICER for a period of three months, from January 1st, 1939, followed by six months' appointment as HOUSE SURGEON (Total nine months.)

Salary at the rate of £100 per annum. Applications to be received by the Secretary not later than first post on Thursday, December 15th, 1938.

November 28th, 1938.

RELIEF OF ECZEMA ★

We have on record many cases where persistent eczema, which had proved refractory, has yielded readily to Sphagnol Peat Ointment. It is commonly known that difficulty in obtaining rapid healing of eczematous conditions is often due to interference by the patient, provoked by the intensive irritation. Particularly is this so with children. Sphagnol Ointment soothes from the first application, giving instant

relief from itching. At the same time, the healing peat distillates which it contains promote the growth of clear, healthy skin.

In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd., Dept. B.M.J.19, 21, Bush Lane, London, E.C.4.

CONTAINS
DISTILLATES
OF PEAT.

Valentine's Meat-Juice

In the Gastric Form of Influenza and its Debility, in Typhoid and Acute Pneumonia, in the Exhaustion of Phthisis and Pulmonary Diseases, Valentine's Meat-Juice Sustains and Strengthens.

When Other Food Fails

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

"DAVON" DRY BATTERY.

Complete in case, £3 12 6.

Or with No. 504 Retino-ophthalmoscope, £7 7 0.

"The outfit is most useful and has worked well." — M.R.C.S., L.R.C.P.

THE "DAVON" (REG. TR. MK.) IMPROVED RECTOSCOPE.

Suggested by Philip H. Dalglish, Esq., M.B., Ch.B.(Ed.), who writes in the "B.M.J."

"Having been dissatisfied for some time by all the various types of proctoscope on the market, I have devised a model for use in the injection of haemorrhoids. The advantages of this new model are that the whole operative field is visible at the same time, that the haemorrhoids do not project into the lumen of the instrument and that there is no obdurator to cause discomfort to the patient and to be a nuisance to the operator. The instrument has been made for me by Messrs. F. Davidson & Co., who are supplying it with illumination from a battery in the handle or from a separate battery.

| | |
|--|---------|
| No. 585. With Washable Rubber Flex ... | £2 15 0 |

The RULE-OF-THREE tonic

1. STIMULATES
2. RE-BUILDS
3. PROTECTS

The immediate and progressive restorative effect of Syrup Minadex may be traced to the reconstructive power of vitamins A and D and minerals (particularly iron and calcium). This nutritive basis ensures that the health rebuilt with Minadex is *positive health*; stimulation being achieved not by alkaloids, but by the factors essential to normal health. The three therapeutic agents in Minadex enrich the blood, strengthen the neuro-muscular system, and fortify the body's powers of disease-resistance. Not a little of the success of this rule-of-three tonic is due to its pleasant orange flavour, free from any hint of fishy oils. The confidence of the patient is assured from the start—a valuable psychological advantage in dealing with 'difficult' patients of all ages.

In 6-oz. bottles, 2/6; 12-oz., 4/6; 80-oz. Winchester, 20/-. Prices (not applicable in Eire) subject to usual professional discount.

WARM, DRY BEDS FOR OPERATION AND ACCIDENT CASES

In cases of sudden emergency and for everyday use, the "Thermega" Electrically-Heated Blanket is invaluable for providing warm, damp-free beds. Hospitals and Nursing Homes throughout the country use "Thermega". It is the one proven remedy for driving out dampness and ensuring warm beds at the turn of a switch.

The "Thermega" Electric Pad for local application is ideal for relief of all pain.

At all good stores, chemists, electricians; or from Thermega Limited, 51-53, Victoria Street, London, S.W.1. (Phone: Abbey 5501.)

TOTAL VITAMIN B ACTION

Disappointing results with Vitamin B₁ given alone, confirm the claim that the entire B Complex should be administered in all deficiency conditions. The B Vitamins form a synergy; each factor contributes to the corrective action. Aluzyme supplies all these factors in a fully active state and is demonstrably the best available source of the complete B Complex. B₁ Potency: 1140 Internat. Units per oz. Active response to nicotinic acid, glutathione and flavin tests. Indications: Avitaminosis B and resulting conditions, anaemias, colitis, many nervous and skin affections.

The New-Eighteenth-Edition of DORLAND'S DICTIONARY

is the Ideal Christmas Present for Doctor, Student or Nurse

**"Unlikely ever to let
its user down," says
"The Lancet"**

"Dorland" is one of those works of reference which has already justified itself by time and usage. It is scholarly, accurate, and comprehensive and within its scope is unlikely ever to let its user down. It is a standby in this office.

—THE LANCET.

**Flexible or Stiff Binding
Plain, 30s. net; Thumb-
Indexed (as illustrated),
32s. 6d. net.**

A complete lexicon of the terms used in Medicine, Surgery, Pharmacy, Dentistry, Biology, Chemistry, Nursing, Veterinary and Allied Fields. Edited by W. A. NEWMAN DORLAND, M.D. Octavo of 1607 pages, 942 illustrations, over 160 in colours, and 100 elaborate tables.

Dorland's Pocket Medical Dictionary

Stands out among smaller medical dictionaries just as does the *Illustrated* in its field. Frequent and thorough revisions have kept it in this commanding position. There are thousands of new terms, dozens of valuable tables, clear definitions, and help of a clinical character for everyone who has to do with medicine, nursing, or allied subjects.

Pocket Medical Dictionary. Edited by W. A. NEWMAN DORLAND, M.D. 16mo. of 920 pages. Flexible binding. 3s. 6d. net, thumb-indexed, 10s. 6d.

SINGLE-HANDED BLOOD TRANSFUSIONS!

The Baxter Blood Transfusion Set gives you complete control of your technique. You need no assistants and no confusing mechanisms. The citrate and blood from the Donor are drawn into a sealed container and the subsequent infusion made from the same container. No chance of contamination or clotting. When surplus blood is accrued from Donor, the excess may be safely stored in the refrigerator by using Baxter's Blood Bank assembly.

FOOT COMFORT

By wearing 'APTERNA' HEEL-LESS SHOES

These shoes are designed in the common-sense knowledge that the majority of foot troubles are due in large measure to faulty footwear which aggravates the trouble and does not permit the natural exercise and freedom which is essential to foot health.

LANGHAM HOUSE, UPPER REGENT ST., W.1

Charles H. Baber

Any of the common foot ailments mentioned in the above diagram can be successfully prevented and relieved by prescribing the correct series of "Apterna" Heel-less Shoes.

"Apterna" Shoes are available for men and women and children.

For Your DEAF Patients

An AMPLIVOX TO WEAR

With CRYSTAL MICROPHONE
STANDARD BATTERIES
WEIGHING ONLY 1½ LBS.
AVAILABLE IN 3 DIFFERENT TONES

The introduction of the Model W AMPLIVOX has a special significance in view of the recent official medical recommendations for valve amplifier hearing aids. It effectively solves the problem of providing a high quality hearing aid with low upkeep costs, offering extreme simplicity and reliability to those who want the smallest possible instrument. It will go into a gentleman's hip pocket or lady's handbag with ease. It can readily be adapted to the Amplivox inductor system for telephone or theatre listening and so provides the most complete hearing aid ever made. I shall be glad to send you descriptive literature if this is not already in your possession.

Prepared for the mouth and throat

'Dettolin' is specially made to kill quickly the micro-organisms concerned in affections of the mouth and throat. It contains, among other ingredients, the active germicidal principle of 'Dettol'—the modern antiseptic. For all its high germicidal efficiency, 'Dettolin' is soothing and gentle on delicate tissue. It has the added advantage of being distinctly pleasant to use, an important factor when frequent and regular gargling is prescribed.

'Dettolin' is obtainable from Chemists and Medical Suppliers.
Price 9d. and 1/3. Sample, and full information on request.

'... a truly marvellous result' - - - M.B. Ch.B.

Thus does a physician sum up his experience in a case of pernicious anaemia treated with Anahæmin B.D.H. In the specific case reported upon, during a period from 12.10.38 to 10.11.38, the red cells rose from 1,350,000 to 4,200,000, the white cells from 2,400 to 4,200, hæmoglobin from 34% to 86%, and the colour index fell from 1.2 to 1.0. These results were achieved by the following dosage; an initial dose of 4 c.c., followed four days later by 1 c.c. and, subsequently, for three weeks by weekly injections of 1 c.c., making in all a total of 8 c.c.

ACETYLCHOLINE B.D.H.

Substitution therapy by the administration of substances chemically identical with the active secretions of the body is a rational form of treatment in many disorders. For example, the administration of acetylcholine, the substance contained in the walls of the intestines which is necessary for the maintenance of intestinal peristalsis, is of immense value in overcoming certain forms

of intestinal paralysis. Acetylcholine is also administered with success in such conditions as Raynaud's disease, embolism of the retinal artery, amblyopias and post-operative abdominal distension. Acetylcholine B.D.H. is a stable preparation of acetylcholine bromide issued in sterilised solution containing 0.1 grm. in each 1 c.c. in ampoules of $\frac{1}{2}$ c.c., 1 c.c. and 2 c.c.

The Treatment of Pyelitis

Remarkable success follows the administration of Mandecal in the treatment of pyelitis, whether acute or chronic; these cases yield to treatment with astonishing rapidity. It is reported that acute cases are free from infection after only two weeks' treatment, whilst chronic infections which have extended over a long period of years, in spite of treatment with many other medicaments, have cleared up entirely after only a short course with Mandecal.

FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research, acetyl-salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has, however, caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that "Alasil" definitely solves the problem of administering acetyl-salicylic acid in an effective form, being free from the risk of irritating the stomach or bowels or of causing general reactions.

A supply for clinical trial with full descriptive literature sent free on request.

In "Alasil" the desirable therapeutic effects of acetyl-salicylic acid are well exhibited by its calcium acetyl-salicylate moiety, while the presence of "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid, obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

THE VACCINE TREATMENT OF PNEUMONIA

P. S. I. VACCINE

(WYNN'S FORMULA)

EVANS

The outcome in pneumonia is largely decided during the first 48 hours and specific treatment is of little, if any, value after the third day. The importance of early specific treatment whether by serum or vaccine is therefore urged.

Vaccine has the enormous advantage that it can be carried in the bag and injected without delay. True lobar pneumonia is less common in many districts than a mixed infection pneumonia, so serum is only available for possibly one-third of all pneumonias.

P.S.I. Vaccine (Evans) is made according to the formula given in the B.M.J., December 22nd, 1934, 1159, and contains in each cc:—

| | | | |
|----------------------|---|---|-------------|
| <i>Pneumococci</i> | - | - | 200 million |
| <i>Streptococci</i> | - | - | 200 " |
| <i>B. influenzae</i> | - | - | 200 " |

P.S.I. Vaccine (Evans) is issued in

To establish a strong positive Iron Balance

Idozan contains 5 per cent. assimilable iron. It is non-constipating and acts in fact as a mild aperient. Idozan is a neutral solution, and exerts no harmful effect on the teeth. A tablespoonful three times a day provides the patient with a daily intake of 2.25 grams of pure iron, and thus establishes, without contra indications, a strong positive iron balance.

Idozan is now made in England, and is regularly prescribed by doctors in no less than fifteen different countries.

IDOZAN

The most extensively prescribed iron preparation in the World.

Packings: 4 oz., 8 oz., 40 oz., and 80 oz. bottles.

VOLPAR

for

VOLUNTARY PARENTHOOD

The introduction of Volpar, the new contraceptive formulated in co-operation with the Birth Control Investigation Committee of the National Birth Control Association, marked an important new development in the history of birth control.

Volpar is the outcome of exhaustive research extending over a period of ten years' continuous investigation; it has been subjected to stringent laboratory tests which show it to be far more powerful than any other spermicidal preparation in use.

Volpar is issued in two forms: **Volpar Gels**—soluble suppositories primarily intended for use alone, or (for maximum safety) with a cap or sheath: **Volpar Paste**—a non-greasy paste for the lubrication of occlusive caps and sheaths or condoms.

Volpar Gels and Volpar Paste, in addition to being thoroughly efficient, are æsthetically unobjectionable.

ZEPHIRAN
TRADE MARK BRAND OF ANTISEPTIC
CONCENTRATE

In many instances the efficiency of an antiseptic varies according to the circumstances in which it is employed, and it therefore follows that few preparations are capable of responding to the many and varied demands arising in every day practice.

Zephiran, however, has been shown to possess a wide range of usefulness in all circumstances, retaining a high bactericidal activity in the most adverse conditions. This characteristic is one of its predominating features, and is possibly the greatest asset an antiseptic can possess.

Probably 70% of all cases of
lobar pneumonia can be treated with—

ANTIPNEUMOCOCCIC SERA

TYPES 1, 2, 4, 5, 7 AND 8

WITH A RESULTANT SAVING of over 4,000 lives
annually in England and Wales.

IN RECENT YEARS an average of 10,000 deaths per year have been attributed to lobar pneumonia alone.

Calculating from the known relative frequencies of the individual pneumococcus types, and from the mortality rate when no serum is given, 22,500 cases and 6,700 deaths are caused by Types 1, 2, 4, 5, 7, or 8, pneumococci.

19 out of every 31 deaths can be avoided* by adequate specific serum therapy, administered during the first four days of illness; in other words, more than 4,000 of these deaths are preventable.

Potent, refined and concentrated "Antipneumococcic Sera Lederle" are available in the following packages:

Bivalent Types 1 and 2, Bivalent Types 4 and 8, Bivalent Types 5 and 7, Monovalent Type 1 and Monovalent Type 2.

A survey of the literature indicates that the types enumerated here are responsible for more than 70% of all cases of pneumococcic infection, no matter how manifested (lobar or bronchial pneumonia, empyema, etc.).

Pediatricists

approve these purées

A range of Strained Foods giving maximum nutritive values

THE nutritional value of vegetable purées for infants and soft diet cases is receiving the endorsement of the medical profession to a very marked degree.

Hitherto the difficulties and deficiencies of home preparation—inefficient sieving and destructive oxidation—not to mention the tedium and labour involved—have hindered practical application, but the introduction of a complete range of strained foods by H. J. Heinz Co. Ltd. has been universally accepted as the solution of this problem.

H. J. Heinz Co. Ltd., with their exceptional experience in food preparation, have recognised the legitimate possibilities of supplying strained foods of that maximum nutritive value, uniformity and convenience which only good factory practice can achieve.

The vegetable and fruit purées of H. J. Heinz Co. Ltd. are prepared under conditions of the most scrupulous care with special reference to minimising mechanical loss of mineral salts and other soluble nutriment. The edible portions are washed and trimmed and then cooked under light steam pressure until in perfect disposition for comminution by extrusion and cutting. All mineral salts, vitamins and other soluble nutriment are retained, while harsher fibres, if any, are so reduced as to be non-irritant. The raw materials are purchased when and where seasonal and regional conditions of growth are most favourable, and only fresh gathered vegetables of the highest quality are used.

After the straining process the purée is adjusted to a proper solid content convenient for marketing. Absorbed air is removed and sealing *in vacuo* follows in specially prepared enamel-lined containers. The process concludes with high-temperature sterilisation.

COD LIVER OIL

DOSAGE AND VITAMIN CONTENT

—THE OFFICIAL RULING

Many practitioners have found that their patients still believe it necessary to take large doses of cod liver oil, and in consequence resort to other liver oils of uncertain origin and widely varying vitamin content. Reference, however, to the latest Addendum (1936) of the British Pharmacopoeia shows that the standard dosage for cod liver oil is very much smaller than conventionally supposed, and, moreover, that a definite vitamin content and origin are specified.

The ruling on vitamin content is that each gramme of cod liver oil shall contain not less than 600 International Units of Vitamin A and not less than 85 International Units of Vitamin D. Given this content, the minimum dose of cod liver oil is fixed at 15 minims (a quarter teaspoonful) three times a day.

The advantages of being able to prescribe a cod liver oil which is guaranteed to conform to this ruling of the British Pharmacopoeia are obvious. The smaller dose is readily acceptable by the patient, which fact makes it unnecessary to resort to other liver oils whose vitamin contents are uncertain both as to origin and efficiency and which have none of the proved food values of cod liver oil.

'SevenSeas' Cod Liver Oil is guaranteed to conform to the British Pharmacopoeia requirements, and it has the additional advantage of being made from absolutely *fresh* livers. The small dose of cod liver oil now needed and the pleasant taste of 'SevenSeas' Cod Liver Oil arise from the fact that 'SevenSeas' trawlers

are equipped to render the oil on board, immediately the fish are caught. This is possible only with cods' livers, owing to their high percentage of oil. It cannot be done with the livers of other fish.

In the case of 'SevenSeas' High Potency Oil, the dosage is reduced to a matter of drops only, for this oil has a guaranteed vitamin content of four times British Pharmacopoeia standard. It is not concentrated or fortified in any way, but is obtained simply by selection from fresh cod livers with a naturally high vitamin content. This High Potency Oil should be of particular interest to practitioners wishing to prescribe for patients who cannot assimilate fat or have a tendency towards acidosis.

All 'SevenSeas' oil is thoroughly tested before being issued to the public. It is prepared and packed in strict conformity with British Pharmacopoeia requirements. Samples of the High Potency Oil, the Standard Oil, and the High Potency Oil in capsules will be sent on request.

HOW WHOLE WHEAT CRISPBREAD BENEFITS HEALTH

WHEAT has always been Man's first choice among the cereals, whenever climatic conditions did not prevent his getting it. That remains true of all bread, either white or wholemeal, either soft or biscuit-crisp. And Vita-Weat, the wheaten crispbread with the WHOLE of the wheat left in it, has advantages which entitle it to a very high place among the staple foods of the world.

Its Calorific Value

Bread is the 'energy component' and Vita-Weat, since it contains only 3 per cent. of water, has a fuel-value nearly twice that of ordinary bread—according to the *Practitioner* its calorie value is 2,132 per lb.

Each section of such a crispbread—each 'slice,' so to speak—has a calorie value of 37. That is to say, that in meeting what is probably the greatest requirement of a national staple food Vita-Weat is almost twice as effective as the softer kinds of wheaten bread.

Starch and Digestion

A crispbread, obviously, calls for a more thorough chewing than a soft 'crumb' bread and salivation is therefore more healthily promoted. The starches and cellulose in Vita-Weat are also 'converted' into a more digestible form by the special processes which go to make a good crispbread—just as toast and crust have become greatly more digestible than bread in its quite 'unconverted' starchy form. While *all* the wheat-berry is used the bran and fibre are thoroughly disintegrated.

The result is, therefore, that the weight which quantities of 'unconverted' starch places on the digestion is almost entirely eliminated where Vita-Weat has been prescribed.

VITA-WEAT AND ITS ADVANTAGES

In addition to these great advantages of superior fuel-value and digestibility Vita-Weat retains the 'protective' elements of the wheat-berry which are frequently rejected in the 'refining' of white flours. Proteins, vitamins and minerals in which bread is normally deficient are present and the 'balance' of this crispbread as a food is therefore increased. The use of Vita-Weat can be shown to be especially desirable in cases of mild anaemia, liability to infection, lack of appetite, poor digestion, diabetes, obesity and as a food of 'protective' value to the teeth.

A little booklet has been prepared for the medical profession briefly summarising the medical case for a whole wheat crispbread and it will gladly be sent post free to any doctor on application to Peek Frean & Co. Ltd., Keeton's Road, London, S.E.16

Intestinal Disorders consequent upon Bronchial Infection

Partly owing to the considerable amount of sputum inevitably swallowed by the patient in bronchial affections (especially in children) disorders of the digestive organs may be produced.

A suitable diet and a free daily evacuation tend to prevent these disorders.

Andrews Liver Salt by its effervescence freshens the mouth (often so dry in bronchitis) and by its antacid reaction counteracts gastric catarrh. By producing an easy evacuation, safe even in the presence of myocardial degeneration, it removes the organisms introduced by the swallowed sputum.

★ *N.B.—A large size tin will be sent free on request to any member of the medical profession.*

Vitamins A, B₁, B₂ and D Calcium and Phosphorus Liver and Malt Extracts

IN ONE PALATABLE PRODUCT

ABBOTT'S HALIVER MALT with Viosterol is biologically standardised for vitamins A, B₁, B₂ and D. Each teaspoonful is equivalent in vitamin A potency to at least one teaspoonful of high grade cod-liver oil; in vitamin D potency to five drops of Viosterol in Oil. In vitamins B₁ and B₂, three teaspoonful are equivalent to at least one cake of moist, compressed yeast. The liver extract in this preparation is a standardised extract and contains the necessary factors for the production of mature red blood corpuscles. The pure barley malt extract supplies diastase and a number of valuable nutritive substances. ● Each fluid ounce of Haliver Malt with Viosterol contains not less than: 27,000 International units of vitamin A; 50 International units of vitamin B₁; 50 Sherman units of vitamin B₂; 7,000 International units of vitamin D; the equivalent of 5 grs. of mono-calcium phosphate; and the equivalent of ½ oz. of fresh, mammalian liver. ● Because the vitamin A and D content of this product is supplied by Haliver Oil (halibut-liver oil, Abbott) and Viosterol, Haliver Malt with Viosterol is entirely free from the disagreeable "fishy" taste to which so many patients object in malt preparations containing cod-liver oil. ● Abbott's Haliver Malt with Viosterol is supplied through pharmacies in 8-ounce and 32-ounce bottles. Requests for professional literature are invited.

'Elastoplast' *elastic adhesive* Plasters are rolled with the adhesive surface *inwards*;

they are clean to handle and to apply, and very convenient when short lengths only are required.

'Elastoplast' Plasters consist of lightweight cotton cloth, spread to the edges, flesh-coloured and rolled on snap spools. They are designed for use as plasters or as dressings for wounds, operation incisions, skin affections, etc. Supplied in all widths from $\frac{1}{2}$ " to 4", $\frac{5}{6}$ yards long when stretched.

'Elastoplast' *elastic adhesive* Bandages are rolled with the adhesive surface *outwards*

to conform with accepted bandaging technique

Made from heavy cotton cloth, selvedge-edged, rolled on card cores, they are suitable for use as bandages for varicose legs, sprains, dislocations, fractured ribs and other cases where complete encirclement of the limb or trunk, with compression, is necessary. Supplied in all widths from 2" to 6", $\frac{5}{6}$ yards long when stretched.

NOTE: If specially required, 'Elastoplast' Bandages can be supplied with the adhesive inwards.

PHYSIOLOGY OF THE VOCAL MECHANISM*

BY

DOUGLAS GUTHRIE, M.D., F.R.C.S. Ed.

Surgeon, Edinburgh Ear and Throat Infirmary; Consulting Aural Surgeon, Royal Hospital for Sick Children, Edinburgh

The problems connected with the mechanism of voice form an interesting study which has hitherto received comparatively little attention from the laryngologist. He tends to rely upon one method of examination—that of inspection, forgetting that the larynx, like other organs, has a function which deserves investigation. The laryngoscope has become almost a fetish, and consequently in this respect laryngology has not kept pace with the sister science of otology, in which the functional examination of hearing is acknowledged to be as essential as inspection of the tympanic membrane. Surely voice production is as important as voice perception.

A Neglected Branch of Laryngology

There are other reasons for this neglect of the study of vocalization. The subject may be approached from so many angles that it is difficult to obtain a comprehensive and unbiased survey. Anatomy, physiology, phonetics, physics, music, psychology are only a few of the sciences involved in a study of voice.

Naturally enough, the literature of the subject is widely scattered. It is not easy to find a synopsis of present-day knowledge of the mechanics of voice. Paradoxical though it may seem, laryngology is strangely aphonic on vocal matters. In vain does one search the modern standard English and American textbooks of laryngology for information on the vocal mechanism and its disorders.

Before laryngology became so aggressively surgical its practitioners displayed considerable interest in speech and song. Morell Mackenzie, Semon, Lennox Browne, and others paid much attention to the problem, and their papers still deserve attention. To-day, speech and voice are again attracting general notice, and it is surely the duty of the laryngologist to make some further contribution to the subject, or at least to acquire some basic knowledge of the physics and the physiology of vocalization in order that he may render the best service to the patient who depends upon his voice for a livelihood.

The Conflict of Singing and Science

Many textbooks of physiology contain a chapter or section on the human voice, and another source of information is to be found in the writings of singers themselves, and of teachers of singing and of speech. Several small manuals have appeared in this country. But it is not easy to describe an art in terms of science. Some of those books show a lamentable lack of physiological knowledge. The best of them are the result of a collaboration of medical and vocal specialists, each contributing his share. Such co-operation is greatly to be desired, as there has long been an unfortunate conflict

between singers and scientists. The singer uses such terms as head voice, tone, register, etc., which mean nothing to the scientist; the scientist, on the other hand, may confuse the singer by concentrating too heavily upon the larynx as the vocal organ, forgetting the equally important factors of respiration and resonance.

Evolution of the Vocal Mechanism

As a unit of the vocal mechanism the larynx is highly evolved, and its performance is truly wonderful. The vocal cords are capable of delicate adjustment by means of numerous muscles, some sixty in number. Even in lowly forms of life one may find sound-producing mechanisms which are the precursors of the highly evolved human larynx.

That supreme vocalist of the insect world, the cicada, so well known in legend and fable, possesses a chitinous plate which is caused to vibrate by the rapid contractions of a powerful muscle, producing a note corresponding to a pitch of 660 cycles per second. The female cicada is dumb; only the male can sing (Baier, 1930).

Certain fishes have a vocal mechanism (Greene, 1924). In the Californian singing fish there is a swim-bladder having two compartments divided by a diaphragm with a small central aperture. On each side of the wall of the air sac is a large muscle controlled by a spinal nerve. Contraction of this muscle forces the air from one chamber to the other, and a sound is thus produced which appears to be purposive. The mechanism resembles that which enables the frog to emit his familiar croak. Birds have a highly specialized vocal organ, the syrinx, with pads at the bronchial bifurcation to act as vocal cords, while the upper larynx is also used in producing song (Haecker, 1898).

I mention these examples merely to show that the human larynx would appear to have a long ancestry so far as its vocal function is concerned.

The Development of Voice

As an introduction to the mechanics of the larynx itself and of the vocal mechanism of which it is but a part, it is necessary to say a few words regarding the development, range, and classification of the voice.

The newborn infant cries on a note approximating to 435 cycles per second, and as growth proceeds the vocal range extends until at the end of the first year it encompasses six half-tones, at the end of four years about an octave, and just before puberty about an octave and a half (Nadoleczny, 1926). A practical deduction from those facts is that the limited range of the child's voice should be more widely recognized by those who compose for children songs which are often ill adapted to their voices.

* The Annual Address delivered at the Central London Throat, Nose and Ear Hospital on October 21, 1938.

Vocal Changes at Puberty

At puberty the male larynx grows rapidly, each vocal cord increasing appreciably in length. The male voice at this stage undergoes the remarkable alteration known as "breaking," which may occupy six months to two years. The change may begin at 8 years of age or may be delayed as late as the eighteenth year.

In boys the vocal pitch falls by one-sixth at its upper limit and by an octave at its lower limit. In girls the change is much less pronounced, is more rapidly completed, and consists merely in a slight extension of the upper and lower limits. Hoarseness is common in boys, and in about 10 per cent. of cases there may be seen a slight redness and swelling of the vocal cords and laryngeal mucosa, which may lead to an erroneous diagnosis of laryngitis.

Various disorders of voice are apt to appear at puberty. For example, there is the persistent falsetto voice which is the result of an incomplete change. In other cases the vocal change is of perverse nature, and this may account for the occasional appearance of the female bass or the male soprano. No vocal change occurs in boys who have undergone early castration, an operation which was at one time largely practised in Italy.

The Classification of Voices

The adult voice is the result of the puberty change, and the voice may be classified, according to its range, as bass, baritone, or tenor in man, and as soprano, mezzo-soprano, and contralto in women. Among the races of Southern Europe there is a tendency to high male voices and low female voices; there the proportion of tenors and contraltos is greater than among Northern races, in which basses and sopranos predominate. Orientals tend to have voices of high pitch, which may account for the falsetto nature of Eastern song.

It is important for the laryngologist to ascertain the nature of his patient's voice, as a common cause of vocal troubles is the adoption of a range or tessitura unsuited to the voice. For example, one may find a baritone who believes that he is a tenor, and who is therefore subjecting his voice to the strain of singing too high a pitch range.

Range of the Human Voice

Taking into consideration all classes of voice, from the deep bass note of the Cossack choir to the shrill pipe of

FIG. 1.—The vocal range in song and speech.

the coloratura soprano, the entire compass of which the human voice is capable may extend over five or even six octaves (Fig. 1). But such extremes are rare, and an

individual voice seldom extends over three octaves, while a range of two and a half octaves is more usual.

In speaking, a range of about an octave is used, and in dramatic speech about two octaves. The average pitch for speech is situated near the lower level of the singing range. In men it is about 140 cycles per second (*d* in music), in women about 243 cycles (musical *b*). The pitch of the speaking voice may be estimated by comparison with the note of the tuning-fork made for the purpose by Edlmann of Munich.

The Three Parts of the Vocal Mechanism

The larynx is only one part of a delicately adjusted combination of organs, all of which possess functions other than that of voice production. It must never be forgotten that the vocal mechanism is a triple alliance of respiration, phonation, and articulation, the last-mentioned being intimately associated with resonance. Treatment applied to the larynx will not remedy faulty breathing or ill-balanced resonance.

No study of vocal function is complete which does not take into account each of the three units which, coupled and adjusted to each other, constitute the vocal mechanism. Before discussing the part played by the larynx in this trilogy, let me say a few words regarding the respiratory and articulatory components of the mechanism.

The Respiratory Mechanism in Vocalization

The vital apparatus of respiration supplies the motive power of the vocal machine. But normal quiet breathing is an involuntary action, and in order to produce voice, a prolonged and controlled act of respiration is demanded. The best means of securing this has been a subject of controversy among teachers of singing from the earliest days of song.

The method most widely used is the whole chest or central breathing, or the old Italian method. Briefly stated, this consists in reinforcing and sustaining the upward expiratory movement of the diaphragm by contraction of the muscles of the abdominal wall. To some teachers this is known as "abdominal press."

The relative extent of costal and diaphragmatic movement may be studied by the pneumograph (Fig. 2). The excursions of tambours, connected with closed tubes encircling the thorax and abdomen, are recorded on a revolving drum. The records thus obtained vary con-

FIG. 2.—The pneumograph.

siderably. As a rule the prolonged expiration is well shown, the diaphragmatic release occurring slightly in advance of the descent of the ribs and cartilages.

The Method of "Rib Reserve"

My colleague, Dr. Robert Curry, and I recently took the opportunity of observing a method of breathing which, so far as we are aware, had not been investigated previously.

It consists in the use of the "abdominal press," but with the following modification. The lower part of the thorax is maintained in an expanded position during the entire act of speech. This is known as "rib reserve." The method is taught by various schools of speech and drama, and it is also recommended by certain teachers of singing. The artistic results appear to be satisfactory, and the method seems to demand no great effort from those who have practised the technique until it has become almost a reflex action. A third tambour connected with the upper part of the chest records the movements of this region, as in the accompanying tracing (Fig. 3), and demonstrates that in the upper costal region

FIG. 3.—The technique of "rib reserve." The tracings, from above downwards, record upper thoracic, lower thoracic, and abdominal movements. Lower thoracic movement is arrested during the act of speech.

movement continues, while it seems to be held in check in the lower costal region.

It was interesting to observe that one of the subjects of our experiment, a trained exponent of the method (trained as a speaker but not as a singer), did not adopt the technique for singing, and when asked to speak a passage immediately after singing, found it difficult to return to the "rib reserve" method, although she was not conscious of any such difficulty (Fig. 4).

FIG. 4.—Effect of singing upon "rib reserve." Song is recorded at A, speech at B, C, and D. Only in the third act of speech (C) was control of the lower ribs regained.

It appears probable that the elevation of the ribs (and their maintenance in a raised attitude), usually attributed to the intercostal muscles, is partly effected by the serratus magnus muscle. Sir Charles Bell (1836) indicated the importance of this muscle in respiration. It possesses a double nerve supply, from the intercostal nerves and from the long or external thoracic nerve, derived from the fifth and sixth cervical segments. Bell named this nerve the "external respiratory nerve" to distinguish it from the internal respiratory or phrenic nerve.

Our results were confirmed by radiography, but it would take too long to describe them in further detail. Suffice it to say that the breathing mechanism must be studied by the laryngologist who would treat disorders of voice. An incorrect method of breathing is perhaps the chief cause of vocal failure.

The "Resonator" Mechanism

Before discussing the mechanical action of the larynx it is necessary to refer to that most important component of the vocal mechanism which, for want of a better term,

is known as the "resonator." Certain writers on the subject of voice go so far as to say that the vocal cords serve merely to regulate air pressure, the actual sound being produced in the paranasal sinuses. The air, blowing across the ostium of each cavity, is said to produce voice. But every laryngologist knows that the ostia are very small, and hidden behind the middle turbinal away from the main air current. Moreover, there is no proof that operative destruction of the walls of the sinuses has any effect on the voice. The strongest argument against the theory is that in song or speech the air does not pass out by the nose, save in the sounds *m*, *n*, and *ng*.

It cannot be denied that such terms as "head voice," "throwing the voice forward," are useful to the singer, but they do not describe what actually happens. The nasal sinuses cannot be regarded as the source of voice, and indeed the nasopharynx and nose cannot even act as "resonators," as the sound does not pass that way. As for the palate, it has been shown that in order to function as a sounding-board it would require to be of great size.

The two resonators are (1) the mouth and (2) the pharynx, and their acoustical features have been studied in great detail by many physicists since the days of Helmholtz. Coupled to the larynx, they act as a sort of loud-speaker horn; without the resonators the laryngeal note is

FIG. 5.—The buccal and pharyngeal resonators in singing the vowel *a* at 420 cycles and the vowel *i* at 170 cycles. Oscillograph record in corner. Note that in each case the nasopharynx is closed by the velum palati; also the great difference in conformation of the cavities on comparing the two films.

weak and indefinite. Brünings observed a case of attempted suicide in which the pharynx had been cut open, the great vessels escaping. When the patient spoke as the wound was held open he made only a weak bleating sound, but when it was closed and stitched he could produce normal speech.

The classical experiments of Müller on the excised larynx, made over 100 years ago, showed the importance of the co-operation of larynx and resonator, and quite recently Husson (1933) has indicated that various vocal defects may arise from imperfect adaptation of the resonators to the larynx. This also explains why the blowing of wind instruments has a deleterious effect on the larynx of the player. Few of those who play wind instruments have good voices, and many of them suffer from recurrent laryngitis.

The wide variations of the size and shape of the pharyngeal resonator are illustrated in the accompanying

x-ray film from Dr. Curry's work (1937), showing the comparison between the shape and size assumed in singing the vowel *a* at a pitch of 420 cycles and that for the vowel *i* at 170 cycles (Fig. 5).

The Problem of "Registers"

The term "register" has led to so much confusion that a definition is necessary. Garcia (1855) stated that a register was a consecutive series of vocal notes which the trained ear could distinguish from another series of notes, and that the quality of the voice changed in passing from one series to another. One of the problems which confront the singer is the elimination of any obvious change in passing from one register to another and the avoidance of a break in effecting the change, which is really a change of mechanism. The position of the larynx alters, as also do the tension and form of the cords. The latter change has given rise to the unfortunate terms "thick" and "thin" register. In the chest register the cords are thick, of weak tension, and the amplitude of vibration is large; in the so-called head register the cords are thin, strongly tensed, and have a small amplitude of vibration.

Three registers are usually distinguished, known as chest, middle, and head registers. The terms are in no case anatomical; they denote the sensations of the singer. He feels the notes of low pitch in his chest and those of high pitch in his head, but that does not mean that they are formed in these parts. It is purely a subjective sensation. By some authorities the head register ("Fistelstimme") has been termed falsetto, and this has led to some confusion. There is still another register for very high notes, known as the whistle register, produced only by some soprano voices. The whistle originates in a small elliptical gap in the anterior third of the glottis.

Mechanics of the Larynx

Let us now briefly consider the mechanics of the larynx itself in relation to voice. Certain adaptations of the pharynx and larynx are necessary in order to produce notes of various pitches, and those modifications are effected not only by the constrictors and other pharyngeal muscles but also by muscles causing (a) movement of the larynx as a whole and (b) movement of the laryngeal cartilages upon each other.

MOVEMENTS OF THE ENTIRE LARYNX

The act of inspiration exercises a downward pull upon the trachea and larynx, the normal tracheal tug. In expiration this pull is relaxed and the pharyngeal resonator is enlarged. This is obviously a passive movement.

The larynx is capable of movement to the extent of several centimetres in a vertical plane. It may be elevated by contraction of the thyrohyoid muscle and of those muscles which raise the hyoid bone (digastric, stylohyoid, etc.), and it may be lowered by the sternothyroid and omohyoid muscles. The downward movement is accompanied by a forward movement, and the pharynx is thus enlarged in a horizontal as well as in a vertical direction.

In the untrained singer the larynx rises as the pitch rises, and vice versa; in the trained singer this movement is reversed, and the larynx may actually descend as the pitch rises.

The descent of the larynx is intimately connected with the manoeuvre known to singers as "covering," which gives a more pleasing tone at certain pitches, owing to an increase of overtones. The downward movement of the larynx (a movement such as occurs in the initial stages of a yawn) occurs at a lower pitch in the closed vowels; that is, first

on *o* and *n*, then *e* and *i*, and finally on *a*. In other words, the larynx is lower in singing *n* than in singing *e*. As a rule the better trained the singer the less does the entire larynx move.

MOVEMENTS OF THE LARYNGEAL CARTILAGES

It is needless to describe to laryngologists the well-known action of the various laryngeal muscles, which act upon the cricothyroid and crico-arytenoid joints. The crico-arytenoid joint, with its curiously shaped articular surfaces, is capable of rotatory or sliding action, the latter being often forgotten in textbook descriptions.

Certain of the muscular actions do not concern joints. For example, the inferior constrictor of the pharynx, bestriding the wings of the thyroid cartilage, may by its contraction narrow the thyroid angle and thus assist to close the glottis. Further, the thyro-arytenoid, most important of all the laryngeal muscles, is to be regarded as an integral part of the vocal cord itself, as it can alter the form, the bulk, and the consistency of the vibrating cord, and so modify the pitch of the note. But obviously it cannot act alone. It is intimately associated with the cricothyroid muscle or external tensor.

The two synergic muscles are shown in the accompanying engraving from Müller's *Physiology*, published in 1832 (Fig. 6).

Fig. 6.—The cricothyroid and thyro-arytenoid muscles, so-called external and internal tensors of the vocal cords.

The cricothyroid muscle approximates the two cartilages by pulling the cricoid upwards, and thus the cords are tensed. It also assists to close the glottis, but only with the assistance of the posterior crico-arytenoid and interarytenoid muscles. The glottis can be closed only if a side-slipping of the arytenoid is prevented by the arytenoid muscle and if the arytenoid is braced back by the posterior crico-arytenoid muscle.

The lateral crico-arytenoid muscle can act either as an abductor or an adductor, depending upon which of the other muscles are in action and upon whether it causes the arytenoid to rotate or to slide. In using the words "tensor" and "tension" as applied to the vocal cords it must be distinctly understood that no idea of stretching is implied. The cords alter very slightly in length if at all during phonation.

The most important fact to remember regarding the muscles of the larynx is that, while they are grouped and paired, each pair does not act as an isolated unit, but always in conjunction with other laryngeal muscles.

Vibratory Movement of the Vocal Cords

The laryngeal muscles do not produce the vocal note. Phonation is an aerodynamic, not a muscular, phenomenon. The muscles merely adjust and hold the cords in a certain position, at a certain tension, and with a certain shape, and the expiratory air current from the lungs does the rest.

Many vague and ill-considered opinions have been expressed on the all-important question of vocal-cord vibration. All sorts of curious theories have been advanced. One school of observers affirmed that sound was produced by the "cyclonic" air currents within the laryngeal ventricles. Others stated that the cords vibrated in a vertical plane. Although our knowledge is still far from complete it is easy to refute such obsolete notions. We now know, for example, that

vocal cord vibration is mainly transverse, and only to a very slight extent vertical.

From time to time the larynx has been compared to various types of musical instrument. It can in no wise be likened to a stringed instrument, as alterations of pitch do not depend upon changes in the length of the cords. To some extent the larynx resembles a reed or a siren, but the resemblance is not very accurate. What actually happens is that the vocal cords forming the glottic margins are approximated and hardened by muscular action; then, by the increasing pressure of air from the lungs, the glottis is opened and some air escapes. By reason of the elasticity of its margin the glottis again closes, and by the rapid succession of these movements of opening and closing a note is produced, the pitch of which depends upon the number of glottic movements a second. The simile of the siren holds good in that the sound is the result of a rapid series of puffs of air. But the number of movements a second depends, in the larynx, upon the rigidity, thickness, and tension of the vocal cord rather than upon the air pressure. The mechanism for altering the vibrating mass such as one finds in the larynx is not present in any musical instrument. Sir Richard Paget has aptly compared the vocal cords to the lips of a trumpeter.

Working Models of the Larynx

Ewald (1913) constructed a number of models to illustrate the mechanics of the larynx which are probably as accurate as any model can be. The accompanying diagram (Fig. 7) illustrates the principle. The elastic edges

FIG. 7.—Ewald's models, to illustrate the mechanism of vocal cord vibration. In model A the parts representing the cords may be caused to vibrate by a blast of air from below. In model B vibration may also be caused by a downward blast.

are set in motion by the upward air current, but in the second model a note may be produced on inspiration as well as expiration. We know that this occurs in the human larynx in humming, crying, laughing, etc., and even during speech the inspiratory voice is used by children and very talkative persons; while certain animals, such as the cat and donkey, can phonate on inspiration.

Perhaps the most accurate model is that which Harless (1853) constructed from two parallel strips of fresh frog's muscle, stretched across the linear opening of a tube so that they might be set in vibration by a blast of air. When the muscles were electrically stimulated to contract the pitch of the note was raised. The experiment has been repeated by Ewald and more recently by Negus, and it illustrates very well the mechanism of the larynx. The pitch of the note is raised by increased tension of the cords, the loudness by increase of air pressure.

It is generally taught that during phonation the arytenoid cartilages are firmly opposed, the cords alone vibrating. In view of investigations by Némai (1916) and of the cinematograph record of Pressman it would appear that this is not so. In the production of low notes the arytenoid edges vibrate along with the cords. Like the laryngoscope, cinematography at the rate of sixteen images per second can only give a picture of the major

phase, although an ultra-rapid technique, giving several thousands of pictures per second, has recently been tried, and would appear to be an ideal means of investigation, though naturally very expensive.

The exact mechanism of vocal cord vibration is best studied by the stroboscope.

The Principle of the Stroboscope

The principle of the stroboscope was applied to the larynx for the first time by Töpler in 1866. Since then it has been used by numerous workers, and their results form a large bibliography, although in this country stroboscopy has not received the attention it deserves. Even those who have had experience of the method are not agreed as to its usefulness. While some regard the stroboscope as merely an interesting toy, others call it the microscope of the larynx, and regard it as the best means of demonstrating the finer movements. As usual, the truth lies between the two extremes.

Stroboscopy consists in the inspection of the larynx by a periodically interrupted beam of light, the number of interruptions per second coinciding or nearly coinciding with the number of vibrations of the vocal cords. A blast of air passing through the slots in the revolving disk gives (after the manner of a siren) a note of a pitch corresponding in frequency to the number of interruptions of the light, and the subject is asked to imitate this note. If, for example, he emits a note of a pitch corresponding to 128 double vibrations per second while the larynx is viewed by a beam of light interrupted 128 times per second the vocal cords appear to be immobile. Then, if the revolving disk is very slightly retarded so that the light is interrupted, say, 127 times per second, the cords are seen to move at the rate of one vibration per second; in other words, the observer views the vocal cords in "slow motion," each interruption contributing a small fraction ($1/127$) of the composite view presented each second. But if the number of light interruptions be slowed down considerably, say to 115 per second, the laryngeal note remaining at 128 cycles, one will no longer see each individual vibration. The less the variation between the interruptions of the light and the vibration of the cords, the more clearly is the movement of the cords demonstrated. By varying the speed of the disk and the pitch of the note produced one may analyse the vibratory movement of the vocal cords.

A stroboscope has been recently introduced in which the source of light is a neon lamp which may be directly controlled by the voice pitch transmitted by a microphone connected to the lamp.

Results of Stroboscopic Examination

It cannot be denied that the stroboscope has added to our knowledge of the physiology of the larynx. By its aid one may study the closure of the glottis, the amplitude of the vibration, the direction of movement, and the form of the cords at the various pitches which the voice may produce.

By means of the stroboscope one may clearly distinguish between a paralysed vocal cord and a cord which is fixed by crico-arytenoid ankylosis. One may diagnose a paresis of the adductor muscles which escapes notice in the ordinary laryngoscopic view. One may note incoordination on various pitches (islands of defective phonation); one may discover a difference in the rates of vibration of the two cords (a phenomenon not yet fully elucidated); and one may study abnormal mechanisms such as ventricular band voice.

Vibratory movement in the vertical plane is characteristic of a paralysed cord, the normal movement being horizontal. The duration of contact of the cords varies

according to the pitch. In 1832 Lehfeldt suggested that there were two vocal cord mechanisms—the normal and the falsetto—and he stated that in the high note of the so-called falsetto register the glottis remained open while the edges of the cords vibrated. Müller confirmed this view, and at a later date Katzenstein (1909) sought to prove that the thyro-arytenoid was the active muscle in the lower register, while in falsetto the cricothyroid took over the work of maintaining the tension of the cords.

Quite recently Tarneaud (Husson and Tarneaud, 1932), using the stroboscope, observed that in the falsetto register the cords did actually make contact, but that the duration of such contact occupied so small a part of the cycle that it escaped notice under ordinary laryngoscopy. Tarneaud's diagram, here reproduced (Fig. 8), illustrates how, in

FIG. 8.—Tarneaud's diagram showing the open and closed phases of vocal cord vibration as revealed by the stroboscope. On the left are sections of the vibrating mass (thyro-arytenoid muscle) during the closed phase from a low-pitched note at 1 to a high note at 4; at 1 and 2 the thyro-arytenoid muscle is contracted; at 3 and 4 the cord mass is smaller and tension is maintained by the cricothyroid muscle.

The diagram on the right shows how the closed phase predominates at 2, and on laryngoscopic examination the cords appear to meet. At 4 the open phase predominates and the cords appear to remain apart. The real extent of movement can be determined only by stroboscopy.

singing up the scale, the open and closed phases of the vibration vary in duration, and how, in falsetto, the closed phase is very brief in comparison with the time occupied by opening and closing of the glottic aperture. It is generally agreed, however, that in the highest notes of the whistle register there does remain a small opening near the anterior part of the glottis during the entire vibration, and this note is produced only by the rush of air through the hole.

Pressman's film (1938), which was shown this year at the Royal Society of Medicine, while of course it did not analyse each vibration as does the stroboscope, showed clearly that on the low notes the posterior part of the glottis, including the arytenoid margins, is vibrating, on the middle notes the edges of the entire cords vibrate, and on the high notes the anterior part of the cords vibrates. The film also shows how the cords were kept moist by a continuous flow of mucus from the laryngeal ventricle, this being probably one of the chief functions of the ventricle. The ventricle also enables the ventricular bands to act as an outlet valve, preventing the escape of air and thus ensuring fixation of the thorax during movements of the upper limbs. This function was first described by Professor John Wyllie (1866) of Edinburgh seventy years ago.

Treatment of Voice Disorders

The physiological facts which I have so roughly outlined are of no mere academic importance. They form an essential background to the diagnosis and treatment of voice disorders. Just as orthopaedics has budded from general surgery, so may orthophonics become a useful branch of laryngology. The laryngologist is often consulted by the singer or speaker who complains that the voice is weaker than usual or becomes easily fatigued or is apt to "crack" at certain pitches. There may be symptoms of local irritation or soreness, of constant clearing of the throat or recurrent hoarseness. On examination one may find the dilated vessels and lymphoid nodules which are sometimes described as the signs of "clergyman's sore throat" but which, if pathological at all, are the result rather than the cause of the trouble. The tonsils may be present and the nasal septum may be deflected, but as a rule some previously consulted colleague has dealt with those structures. Most often local examination reveals no abnormality, and the laryngologist is content with the diagnosis of a "functional disorder" and sends the patient to a singing teacher or to a speech therapist. Such a diagnosis is correct: it is indeed a functional disorder—phonasthenia, if we choose to name it so—and the treatment also is sound, as a good speech therapist knows how to deal with the case. But one ought to go further and endeavour to ascertain what part of the vocal mechanism is at fault. Is it the method of breathing? Is it the vocal range? Did the trouble originate from overstrain of the voice or from use of the voice in the course of a cold or after an illness? The laryngologist must not regard his patient as a larynx surrounded by a body, and he must even inquire into the environment of the body with a view to discovering any feature which has an influence upon the voice. The prescription of a spray is not enough, though it may be of great psychological value. Orthophonic treatment must be directed towards the correction of disordered function, and must necessarily be on a physical basis.

Conclusion

And so I conclude this address as I began it, with a plea for a closer study of the problems of speech and of voice, and for a fuller recognition that the vocal mechanism—using the term in the widest sense—still offers a great field of study for the laryngologist. One often hears it said that laryngology is a narrow specialty and that it must needs constantly invade other anatomical territory. What more interesting research could be found than that which concerns vocal function? In pursuing such a study the

laryngologist is in the very centre of his own domain, but even here there is a territory which has too long been left unexplored.

I desire to record my indebtedness to the superintendent, Royal College of Physicians Laboratory, and to Professor Drever, Department of Psychology, University of Edinburgh, for their kindness in providing facilities for histological and experimental work.

VI AGGLUTINATION IN THE DIAGNOSIS OF TYPHOID FEVER AND THE TYPHOID CARRIER CONDITION

BY

S. S. BHATNAGAR, M.D.Laus., Ph.D., M.R.C.P.,
Major I.M.S.

Deputy Assistant Director of Pathology, Deccan District,
and Officer in Charge, Deccan District Laboratory,
Trimulgherry, India

Our conception of the diagnostic significance of a Widal reaction has materially altered since it became known that the typhoid-paratyphoid group of organisms are possessed of more than one antigenic component—notably the flagellar H antigens and the somatic O antigens, which produce their serum counterparts on human infection. Since the great war a complicating factor in the serological diagnosis of the enteric group of fevers has been introduced by the widespread use of T.A.B. inoculation.

The relative importance of the two types of antibody (O and H) in the diagnosis of typhoid fever, and of other enteric infections, in the inoculated and the uninoculated individual, first demonstrated by Felix (1924), has been the subject of a large number of studies, the literature being fully summarized by Topley and Wilson (1936). As a result it is being realized that in the interpretation of serological tests such diverse factors as the natural level of O and H agglutinins, the state of the subject in relation to previous inoculation, the agglutinin curves, the individual titres of the antibodies, and the possibility of non-specific stimulation of antibody formation, have to be taken into consideration.

In the laboratories of the Army in India Widal reactions are carried out as a routine every fourth day throughout the course of a continued fever, against standard O and H suspensions supplied by a central enteric laboratory at Kasauli. From personal experience and from a study of the carefully kept records of cases of typhoid fever for the past five years, it was observed that in a typhoid infection in the inoculated the trouble taken in estimating the O and the H agglutinins could not be justified when the value of the results obtained was assessed. In a large

majority of cases the rise in the titre of these agglutinins offered no tangible evidence from which alone a positive diagnosis could be arrived at. Reliance had therefore to be placed on the isolation of the infecting organism from the blood, the urine, or the faeces. Where this failed, one was commonly confronted with a positive clinical picture and doubtful serological findings. The results proved to be so disappointing that the practice of carrying out tests for the detection of H agglutinins has recently been entirely discontinued in the Army in India.

It is now generally recognized that, apart from the O and the H antigen, the great majority of strains of *Bact. typhosum* possess a third antigen—the Vi antigen—described and designated as such by Felix and his co-workers. A number of strains alleged to be free from Vi antigen were collected by us and grown on a medium consisting of mutton digest agar (2 per cent.) to which 1 per cent. saccharose was added. They all showed the presence of this antigen and gave rise to Vi antibody on animal inoculation.

Serological analysis of sera over the past three years from patients suspected to be suffering from typhoid fever suggested the possibility that Vi agglutination may prove to be a more reliable method of serological diagnosis of typhoid infection than the time-honoured O and H types of agglutination. This view was further strengthened by the observation that in the examination of thousands of sera from both inoculated and uninoculated persons no Vi antibody could be detected. The explanation why this antibody is not produced in spite of the inclusion of a Vi-containing typhoid strain in a T.A.B. vaccine has already been given (Felix and Bhatnagar, 1935; Bhatnagar *et al.*, 1937). Thus no interference was anticipated in the interpretation of serological tests from Vi antibody which could be accounted for either as a natural or as an inoculation agglutinin.

The present communication deals with the demonstration of Vi antibody in 134 cases of bacteriologically proved typhoid fever. The material was collected from both the inoculated and the uninoculated. In addition, information obtained on the bearing of Vi agglutination on the typhoid carrier condition is included.

Detection of Vi Antigen in a Typhoid Organism and of Vi Antibody in a Serum

When an organism with the morphology and the biochemical reactions of *Bact. typhosum* is found to agglutinate with a typhoid O serum much below the established titre of the serum the presence of Vi antigen in the culture is to be suspected. This is confirmed if it gives a positive reaction in agglutination with a pure Vi serum—that is, a serum prepared against a highly virulent strain of *Bact. typhosum* and from which the O and the H antibodies have been completely removed by absorption.

While the detection of Vi antigen can thus be carried out comparatively easily, the titration of Vi antibody in a serum, on the other hand, is complicated by the simultaneous presence in it of O and H agglutinins. Two methods are usually employed to overcome this difficulty: (a) Complete absorption of O and H antibodies from the serum by the use of a strain devoid of Vi antigen. In our experience very few strains indeed are completely devoid of Vi antigen; moreover, this method is a laborious process, hardly of practical applicability to an investigation which involves the serological analysis of a large number of samples. (b) Agglutination against selected strains or their chemically treated suspensions sensitive to one type of antibody only. While alcoholized

and formalized suspensions have proved to be excellent reagents for the titration of the O and the H agglutinins respectively, the real difficulty met with in the routine practice of Vi agglutination has been the want of a strain which either in the live state or as a preserved suspension would react only with the Vi antibody. In the course of the antigenic analysis of 235 typhoid strains, collected from different parts of the world, we were able to identify one culture which in its agglutinating reactions behaved as a pure Vi variant of *Bact. typhosum*. This strain has been designated "Vi I" and is described elsewhere (Bhatnagar *et al.*, 1938). Its agglutination reactions with pure O, H, and Vi sera are exemplified in Table I. This strain is not only insensitive to O and H agglutinins but is also more sensitive to Vi antibody than the well-recognized typhoid strains hitherto employed for the purpose of Vi agglutination—namely, "Ty 2," "Watson," and "6 S."

Vi Antibody in the Blood Serum of Typhoid Patients

The 134 cases of typhoid fever described here consist of fifty-six inoculated and seventy-eight uninoculated individuals. The serum from each case was collected every fourth day and titrated for the presence of the three types of antibody (O, H, and Vi). Table II summarizes the highest titres obtained during the course of typhoid infection; the "titre" represents the dilution of the serum which gives a *one plus* (+) reading according to the agglutination technique of Felix. The O and H agglutinin titres are omitted, as they are intended to form part of a subsequent communication.

TABLE II.—Vi Titre in Typhoid Patients

| Titre | Number showing a Particular Titre | | Height of Titre per 100 Individuals | |
|-----------|-----------------------------------|--------------|-------------------------------------|--------------|
| | Inoculated | Uninoculated | Inoculated | Uninoculated |
| 1 : 10 | — | — | — | — |
| 1 : 25 | — | 27 | — | 34.6 |
| 1 : 50 | 10 | 45 | 17.8 | 57.7 |
| 1 : 100 | 37 | 6 | 66.1 | 7.7 |
| 1 : 200 | 9 | — | 16.1 | — |
| 1 : 500 | — | — | — | — |
| Totals .. | 56 | 78 | | |

It is evident from Table II that Vi antibody was present in the serum from every case of typhoid fever, whether previously inoculated or not. A distinct difference was, however, seen to have been caused by inoculation, so far as the titre of this antibody is concerned, in that the inoculated individuals generally gave a higher reading. Whereas in the uninoculated more than 90 per cent. of the cases examined did not show a titre higher than

1 in 50—34.6 per cent. of these reacting only in the dilution 1 in 25—among the inoculated, on the other hand, a titre of 1 in 100 was obtained in as high a percentage as 66.1 and that of 1 in 200 in another 16.1 per cent. It was noticed that those individuals who have had the benefit of multiple inoculations recorded, as a rule, a higher titre than those who had undergone a single course.

Advantage was taken in sixteen cases (eight inoculated and eight uninoculated) to bleed the patient every third morning so that the development of Vi antibody could be studied every forty-eight hours. Two sample cases are illustrated in Charts I and II.

CHART I.—Showing the development of Vi antibody in an inoculated person.

CHART II.—Showing the development of Vi antibody in an uninoculated person.

It is seen from the charts that the Vi antibody response was different in the two types of individual. In the inoculated the rise of the Vi agglutinin curve was steeper, more Vi antibody was produced, and the highest point was reached much earlier (on the tenth day in this case); in the uninoculated the rise was much more gradual, and the highest titre (only 1 in 50, compared with 1 in 100 of the inoculated person) was not reached till the eighteenth day. It is of interest to note, however, that the fall of the curve was rapid in both cases.

These two curves exemplify what has been observed by us in an average inoculated and an average uninoculated case in which the typhoid fever takes what may be described as a normal course. Departures from the normal in the clinical course of the disease were noticed to produce variations in the elaboration of the Vi antibody as well. Thus in an inoculated community like the Army

it was common to see the infection follow a modified course in which the symptoms were mild and the pyrexia did not last more than eight to ten days. Here the rise of the Vi antibody curve was observed to be much more steep, and so was the fall, the difference in the titre in the course of twenty-four hours being as much as four times. Thus it was not unusual to find a titre of 1 in 100 one morning to be followed by a reading of 1 in 25 the day after.

Typhoid fever in an uninoculated individual in India commonly presents a textbook description of this disease—namely, a step-ladder type of pyrexia, the typical rash, the tympanitic abdomen with "pea-soup" stools, and complications like severe mental disturbances, haemorrhage, and relapse. It was noticed as a rule that the titre of Vi antibody continued to be low till late in the disease in those cases where either the clinical course was severe or the pyrexia prolonged, or a relapse set in later.

From the point of view of the diagnosis of acute typhoid condition with the aid of Vi agglutination, it has been our experience that in an inoculated community a definite conclusion can be arrived at by the end of the first week. The Vi titre was found by then to have been in the region of 1 in 25 to 1 in 50, which could be easily detected with the help of the strain "Vi I."

In an uninoculated population a positive Vi agglutination reaction is of definite diagnostic value. A negative result, on the other hand, cannot be relied upon to exclude the presence of typhoid infection, since the Vi antibody is produced with difficulty in this type of individual and at a much later date during the course of the infection. In a case which runs an uninterrupted course frequent serological tests will, however, detect the presence of this antibody at a titre of 1 in 10 to 1 in 25 during the second week. In cases which relapsed it was noticed that generally no Vi antibody could be found during the primary rise of temperature, a positive Vi agglutination being obtained only during the course of the secondary rise.

Before the identification of the strain "Vi I" the Vi titre of a serum was determined by testing it against three different strains of *Bact. typhosum*, sensitive to O, H, and Vi agglutinins respectively, and the reading of the Vi reaction was taken in the simultaneous presence of O and H agglutination. Where the Vi titre was low the alternative method of completely absorbing the serum of its O and H antibodies was resorted to. This procedure inevitably resulted in the reduction of the already low Vi titre of the serum due to non-specific factors. Further loss took place owing to the absorption of a certain amount of Vi antibody by the small amount of Vi antigen present in the so-called Vi-free organisms that are employed for this purpose.

In view of these technical difficulties in assessing the Vi antibody content of a serum it can be easily understood why the study of this antibody in human infection has not progressed beyond its simple recognition by a few observers (Felix *et al.*, 1935; Bensted, 1937; Lewin, 1938). To start with, the impression was gaining ground with us that the Vi antibody is produced in a large number of inoculated individuals but very rarely in those who are not inoculated. It has only been possible to demonstrate the presence of this antibody in every case of typhoid fever since pure Vi agglutination has been obtained with the help of the strain "Vi I," which is sensitive to the Vi antibody but is insensitive to the O and the H agglutinins in as low a dilution as 1 in 10 (see Table I).

Up to the present we have not failed to correlate a positive Vi agglutination reaction with either the isolation

of the infecting organism or with a positive clinical picture of typhoid fever where bacteriological proof of the presence of typhoid infection could not be obtained. The great advantage of this type of agglutination lies in the fact that a positive result clinches the diagnosis of typhoid fever, there being no interference in the interpretation of the serological test from either the normal or the inoculation agglutinins such as occurs with the O and the H types of agglutination. In a recent personal communication Bensted expressed the opinion that T.A.B. inoculation does give rise to Vi antibody, but only in very small amounts, not large enough to be taken account of in Vi agglutination. On this basis he compares the altered Vi antibody reactivity of an inoculated individual to typhoid infection to the very rapid response to diphtheria toxin when there are minimal amounts of antitoxin in the blood.

It is necessary to emphasize certain technical points in connexion with the quantitative estimation of the Vi antibody. Dreyer's tubes are not suitable for Vi agglutination tests. The type of tube with a round bottom, employed in Felix's technique for the differentiation between O and H agglutination, is most suitable for Vi agglutination. The tubes are about 5 cm. long and have a uniform internal diameter of about 1.25 cm. The difference between the agglutinated bacteria and those that have simply settled down can be easily made out in these tubes, since they permit the shaking of the whole serum-suspension mixture. The clumped bacilli in Vi agglutination have a tendency to distribute themselves round about the lowest quarter of an inch of the agglutination tube, where they appear as a general haze to the naked eye. When the tube is shaken these agglutinated bacteria become readily visible as a considerable mass of somatic agglutination.

With a view to preparing sterile suspensions of strain "Vi I" suitable for Vi agglutination various chemical reagents were tried. None of them has so far proved to be entirely satisfactory. The agglutinability of the organisms so treated diminishes rapidly. Formalized suspensions (0.5 c.cm. of pure formalin added to every 80 c.cm. of the suspension) or those prepared with mercury perchloride (1 in 1,000 HgCl₂ in normal saline) can, however, be trusted to give reliable results for a period varying from four to ten weeks. It is therefore necessary that the Vi sensitivity of the suspension should be tested every few days against a pure Vi serum of known titre.

Vi Agglutination in Detection of the Typhoid Carrier Condition

During convalescence from typhoid fever it was observed that, as a rule, only traces of Vi antibody could be found in the serum. In a certain number of cases, however, the Vi titre continued to be high in spite of the termination of the acute infection. Further investigations revealed that this variation connoted a tendency towards the typhoid carrier condition. It was possible to study the serum reactions of four such individuals over a period of one year side by side with the examination of their stools and urine for the presence of the typhoid organism. None of the patients gave a history of previous T.A.B. inoculation. Three of them were faecal carriers and one urinary. Specimens were obtainable at approximately one-month intervals. The results are reproduced in Table III.

A correlation between the typhoid carrier condition and the presence of Vi antibody in the serum is evident from this table. Individual No. 1 proved to be only a tem-

porary carrier. After the third month no typhoid bacilli could be isolated from his urine or his faeces, nor could the Vi antibody be demonstrated in his serum. The three persons whose serum continued to give a positive Vi reaction proved to be true chronic carriers. The typhoid bacilli isolated from their faeces were invariably found to be virulent Vi-containing organisms.

Pijper (1930), Ashby (1931), Wyllie (1933), and others have suggested the estimation of O agglutinins for the detection of the typhoid carrier condition. The O titres in our series appear to be significantly high. But when this observation is considered in conjunction with the normal level of the typhoid O agglutinin in India, which has been shown to be as high as 1 in 100 in 64 per cent. of the individuals examined (see Bhatnagar *et al.*, 1937), the figures reproduced in Table III, obtained by the same technique of agglutination, cannot be taken to be more than suggestive of the chronic typhoid carrier condition.

The suggestion that possibly Vi agglutination may be a useful method of detecting chronic typhoid carriers was made by Felix, Krikorian, and Reitter (1935), and was followed up by Giovanardi (1936, 1937) in Italy and by Pijper and Crocker (1937) in South Africa. More recently the results of the examination of a considerable number of chronic carriers were published by Felix (1938). I myself have been using Vi agglutination in the routine carrier examination of a large number of individuals, such as is done in the Army in India, and in tracing the source of infection of a particular case or a group of cases of typhoid fever. The detection of Vi antibody in a serum is taken to be an indication for a thorough search for typhoid bacilli in the stools and urine. We have not yet come across an individual who while excreting typhoid bacilli failed to produce evidence of the presence of Vi antibody in his serum. The procedure not only led to the saving of a considerable amount of time and material, but also reduced the chances of missing a carrier in whom the discharge of bacilli was intermittent.

Summary

A strain of *Bact. typhosum* which gives rise to pure Vi agglutination has been identified.

With the help of this strain the Vi antibody is shown to be produced in every case of typhoid fever, the inocu-

lated individuals producing a higher Vi titre than the uninoculated.

Vi agglutination is shown to be a more reliable method of diagnosing typhoid fever in the inoculated than the time-honoured O and H types of agglutination.

A correlation between the typhoid carrier condition and the presence of Vi antibody in the serum is described. The employment of Vi agglutination in the routine carrier examination and in tracing the source of typhoid infection is suggested.

I wish to express my indebtedness to Colonel J. Taylor, D.S.O., C.I.E., V.H.S., I.M.S., Director, Central Research Institute, Kasauli, India, for his kind help and valuable criticism.

With the October issue the *Jahrbuch für Kinderheilkunde* has become an international journal under the editorship of Dr. E. Freudenberg of Basle, published by S. Karger at Basle. Its other titles are *Annales Paediatrici*, *International Review of Pediatrics*, and *Revue Internationale de Pédiatrie*. The journal is open to receive articles in German, English, or French, and each paper will be summarized in these languages. The editorial board consists of representatives from Turkey, Switzerland, United States, Poland, Holland, Yugoslavia, Palestine, and France.

HYPERSENSITIBILITY TO BASAL ANAESTHETICS*

BY

B. P. HILL, M.B., Ch.B., D.A.

The investigation of problems arising in basal anaesthesia is very difficult, since so many factors go to make up the complete anaesthetic record of each case. To mention but a few of these factors, one may say that the patients are often in an abnormal state, either physically or psychologically, before the drugs are given; also, that in some cases other drugs are used in addition to the basal anaesthetic, and these complicate the picture. Furthermore, different operative procedures produce widely different effects upon patients, and these effects might be attributed in some cases to the method of anaesthesia and the drugs used. In view, therefore, of the difficulties to be encountered it would seem that accurate and full records of a large number of cases might furnish a valuable weapon with which to attack the problems involved. By observing factors that are common to many cases which react abnormally to basal anaesthetics, deductions as to their cause and prevention might be made. Perhaps it is no exaggeration to say that the drugs to which very few persons are hypersusceptible are the most difficult to investigate. An example of this is the use of paraldehyde: cases of hypersusceptibility to that drug are comparatively rare; but they do occur, and are very hard to explain, because comparison of common factors is almost impossible.

Avertin

Cases which are hypersusceptible to the action of this basal anaesthetic are more often seen, but are by no means common. As a result we know a little more about the causes of the hypersusceptibility to avertin. One of the most dangerous forms which this hypersusceptibility takes, but not the most common, is perhaps that of liability to liver-cell damage. In view of the similarity in chemical structure between avertin and chloroform, the comparison of their toxic effects is interesting. Both have a tendency to cause necrosis of the central cells of the liver lobules. The symptoms are very much the same with both drugs, and in the case of chloroform constitute what is known as delayed chloroform poisoning.

It has recently been shown that the liver extract of animals contains a substance which is able to protect liver cells from damage by small doses of chloroform. This substance has been isolated, and found to be sodium xanthine. When injected into animals sodium xanthine protects the liver cells from much greater doses of chloroform than those necessary to produce necrosis in normal animals. It is not unreasonable to suppose that the livers of people showing this form of hypersusceptibility to avertin might be deficient in this cell-protecting substance.

A recent case at the Royal Berkshire Hospital showed quite obvious symptoms of liver-cell damage following a dosage of avertin of 0.1 gramme per kilogramme of body weight. The patient recovered, and it was found later that she had revealed almost identical symptoms following chloroform anaesthesia twelve years previously. On the first occasion pure chloroform had been administered for thirty-five minutes; at her recent operation no chloroform was used.

* Paper read to the Section of Pharmacology at the Annual Meeting of the British Medical Association, Plymouth, 1938.

The above illustrates the use that might be made of the previous anaesthetic history of a case to indicate a possible hypersusceptibility to avertin or any other basal anaesthetic.

The Barbiturates

In a series of 300 cases in which nembutal, sodium evipan, and sodium amylal were used forty-six showed hypersusceptibility in some form or other. The most common symptom was that of severe post-operative restlessness, for the control of which morphine was required in many cases. The next most common form was that of prolonged narcosis, which in one instance lasted for nineteen hours.

Other symptoms that suggested hypersusceptibility were:

- (a) Respiratory depression, which resulted in cyanosis in two cases.
- (b) A fall in systolic blood pressure to 90 mm. Hg.
- (c) The appearance of albuminuria, which persisted for four days in a patient previously albumin-free.
- (d) An increase in bronchial secretion, which resulted in cyanosis in a patient whose supplementary anaesthetic was nitrous oxide-oxygen only.

Certain conditions and diseases seemed to favour hypersusceptibility to a barbiturate, but they were by no means constant in the effects produced. They included:

1. Arteriosclerosis, especially when accompanied by high blood pressure.
2. Senility, even in the absence of obvious pathological changes.
3. Anoxaemia of the body tissues.
4. Toxaemia of bacterial origin. This was especially marked in the toxaemia due to the haemolytic streptococcus.
5. The presence of shock.
6. Pulmonary disease.

The use of the barbiturates in cases showing clinical evidence of hepatic disease was avoided.

Thirty-six cases of the series in which hypersusceptibility was suspected were given sodium amylal in a dose of half a grain per stone of body weight. Where necessary this amount was administered in a divided dose, and the effect of each dose was carefully observed. In twenty-four of these patients the suspicion proved to be justified, because twenty-two of them showed severe post-operative restlessness and two prolonged narcosis. These results suggested that although in some cases hypersusceptibility might be anticipated, this anticipation proved correct in only about 66 per cent. of cases.

It is probable that hypersusceptibility in an individual varies within wide limits. Some of the patients in this series had had repeated operations, and the same dose of the same drug was given on each occasion, the conditions being kept as nearly constant as possible. Fourteen cases were investigated thus, and not one showed hypersusceptible tendencies twice, though three patients had abnormal reactions to the drug on one of their visits to the operating theatre.

Another factor which seemed to influence the appearance of hypersusceptibility was the route by which the drug was administered. When given intravenously nembutal produced shorter periods of post-operative restlessness in certain susceptibles than when the oral route was used, but the symptoms appeared very much earlier after operation and were usually more severe. Prolonged narcosis and respiratory depression were more frequent

when the intravenous route had been used. All cases in which the drug was given intravenously showed temporary albuminuria. In one case this persisted up to the fourth day.

The muscular contractions that were fairly common during and following the injection of evipan were not seen with nembutal used intravenously to the point of loss of consciousness. One out of the six healthy men who each received a fairly rapid intravenous injection of 10 c.cm. of cold sterile normal saline had an attack of shivering following the injection. This led to the inference that perhaps these muscular tremors are not a manifestation of hypersusceptibility to evipan in all cases.

In an attempt to detect hypersusceptibility to a barbiturate a test rather similar to the Schick test was devised. This was used in 210 cases. Into the skin of the forearm was injected 0.2 c.cm. of a 10 per cent. solution of sodium amytal, a control injection of sterile saline being made at the same time. The sites of injection were observed for the appearance of erythema. The results showed the unreliability of such a test in a very striking manner.

Conclusion

Hypersusceptibility is rare with the use of paraldehyde as a basal anaesthetic. Its explanation is very difficult in consequence, and cases are hard to anticipate.

More undue susceptibility is seen when avertin is used, and therefore rather more information as to the cause and avoidance of symptoms is available. Hypersusceptibility results in liver-cell damage in certain cases, and this may be due to the deficiency of a substance which normally protects the liver cells from necrosis during the detoxication of avertin.

With the barbiturates, hypersusceptibility is very inconstant, even in the same individual. Certain factors favour an undue reaction to a normal dose of the drugs, and though not absolutely constant these factors must be considered as a guide to dosage. No reliable test has so far been devised by means of which hypersusceptibility may be detected, and a skin test proved to be wholly unreliable.

Summary

It is suggested that deductions as to the cause and the prevention of hypersusceptibility to basal anaesthetics might be made by observing common factors in a large series of cases.

The liability to liver-cell damage from the use of these drugs is discussed.

Certain diseases and symptoms that suggest hypersusceptibility are recorded.

The route of administration is discussed as a factor in hypersusceptibility.

At the first public exhibition of its kind in the United States of America, held at the Harlem Art Center in New York City under the auspices of the Government's Federal Art Project and of the Bellevue Hospital's Psychiatric Division, 106 pictures were shown as the work of disordered minds. The artists included moronic children, chronic alcoholics, advanced epileptics, schizophrenics, manic-depressives, and victims of G.P.I. The majority of the exhibits told of mental conflicts and had but scant contact with reality, being shapeless (sometimes senseless), lurid, and gruesome. The idea underlying the art classes at Bellevue is to attempt a cure of the mentally sick by encouraging them to express their conflicts and at the same time to give psychiatrists a clearer picture of their patients' emotional life.

TREATMENT OF ACUTE OSTEOMYELITIS BY ULERON

BY

ALEX. MITCHELL, Ch.M.

*Lecturer in Surgical Diseases of Children and Orthopaedic
Surgery in the University of Aberdeen*

My object in writing this note is not merely to record a short series of successful cases but to draw further attention to the use of uleron in the treatment of osteomyelitis. If it is of the value which I for the present am led to believe that it is, my belief can be confirmed by the observations of others, who I hope will put it to trial if they have not already done so.

The treatment of acute septic osteomyelitis demands the consideration of three problems: the relief of the abscess which is usually present; the treatment of the general infection, which in many cases manifests itself in the form of a virulent septicaemia; and the best method of dealing with the actual bone infection, which, although apparently responding satisfactorily to local treatment, may show a persistent tendency to recur, and this over a period limited only by the patient's span of life. For many years I have been interested in these problems, and after a close examination of the subject it seems to me that we cannot honestly maintain that our treatment has advanced much during the last twenty-five years, if we are to take as our criterion a highly improved mortality rate and an increased freedom from late recurrence of infection.

Practical experience over a long period improves one's judgment as to when to operate and as to the type of operation suited to each particular case; but it has been found that sera and blood transfusions are of very little value in the treatment of the severer types of septicaemia, and we still have to rely on Nature's powers of clearing up such infections. The liability of cases apparently completely cured to show severe and intractable recurrences years afterwards has, in my opinion, never received sufficient recognition. It is the knowledge of this liability to recur that has caused me always to be an advocate of complete subperiosteal resection in suitable cases.

The various forms of treatment advocated from time to time are familiar to us all, but the fact that they show such variety must surely mean that no one of them has been found to provide a complete solution to our difficulties. Hitherto no specific agent has been discovered that will really influence the staphylococcal septicaemia so often present, but my experience during the last year has led me to wonder whether we have not at last been offered something which, from the limited trial I have been able to give it, appears to be a curative agent worthy of more extended trial.

Five cases of acute osteomyelitis have been treated with uleron in addition to the ordinary local treatment. This drug, a sulphonamide preparation made by Bayer Products Ltd., has been used in tablet form (7½ grains). To young children we have given one tablet every four hours. The period over which it has been administered has varied up to several weeks.

The cases treated are few in number, but may be considered representative cases because they are all of the really severe type of osteomyelitis, and in each of four of them a different method of operative treatment was adopted; in the other no operation was done. Four were treated in the Royal Aberdeen Hospital for Sick Children, one in a nursing home.

Case I

A girl aged 11 was admitted to hospital on December 13, 1937, with a history of three days' illness—typical acute osteomyelitis of the lower end of the right femur with abscess formation. The child was very ill, and had a temperature of 102° and pulse of 126. An incision was made down to the bone, which was not drilled (Mr. S. G. Davidson). On the 17th there was pain and swelling of the left tibia, followed on the 18th by pain and swelling of the right humerus. Uleron, $7\frac{1}{2}$ grains, was given three daily for about a week, beginning on December 17. Three days after uleron was started the temperature began to fall and the general condition rapidly improved. There was no operative treatment for the tibia or humerus. The patient was discharged in April, 1938, with the wound in the right leg healed.

Skigrams showed the typical appearance of osteomyelitis in the femur, tibia, and humerus. *Staphylococcus aureus* was found in the pus. The report from a blood culture was negative, but there must have been considerable blood infection, as proved by the appearance of two very definite secondary foci.

Case II

A boy aged 4 was admitted to hospital on July 15, 1938, with a history of three days' illness, and also of swelling and pain at the lower end of the femur. The appearance was typical of osteomyelitis; temperature 102° , pulse 160. The child was gravely ill, and it was considered that any operative procedure was not justified. Uleron was given every four hours and continued for three weeks, when the child's face began to look rather bluish and use of the drug was discontinued. Two days after uleron was started his condition began to improve, and his temperature fell to normal in a week.

Skigrams showed periosteal thickening at the lower end of the femur and, later on, a small focus in the shaft higher up. Blood culture showed the presence of *Staph. aureus*. The child was discharged one month after admission apparently cured.

Case III

A male child aged 2 was admitted to hospital on June 23, 1938, having a history of two days' illness, with pain and swelling at the upper end of the left tibia and an abscess. He was very ill, his temperature being 104° and his pulse 160. Uleron, $7\frac{1}{2}$ grains, was given every four hours. On June 27 the abscess was incised down to the bone, and on July 20 the whole shaft was easily removed subperiosteally. A small part of the circumference of the shaft was sawn off in all its length, boiled, and replaced in the periosteal bed. Pus and blood culture made on June 27 showed *Staph. aureus*, but on July 6 blood culture was negative. A small secondary abscess developed in the lower end of the right radius, but this cleared up quickly after being drilled. On August 19 the leg wound was very clean. The granulations were exceptionally fresh-looking, and the tibia was re-forming in very good position.

Case IV

A youth aged 16 was admitted to a nursing home on July 21, 1938, with pain and swelling of the lower end of the right femur. The temperature was 106° and pulse 120. The abscess was incised on the same day. Four drill-holes were made and a small piece of the cortex of the femur was removed. Uleron, $7\frac{1}{2}$ grains, was given every four hours. Blood culture was positive to *Staph. aureus*. A second blood culture on August 1 was negative. This patient showed a very rapid improvement, but uleron had to be discontinued after eight days owing to skin irritation.

Skigrams showed that a considerable length of the shaft of the femur was infected. On August 18 there was very little discharge from the wound and the patient's general condition was excellent.

Case V

A boy aged 6 was admitted to hospital on August 10, 1938, having a history of two days' illness. His temperature was 102° and the pulse 138. There was pain and swelling over the lower end of the right femur, and the abscess was incised. Two drill-holes were made in the lower end of the femur; acriflavine and vaseline gauze dressing were applied and the leg fixed in plaster-of-Paris. Uleron, $7\frac{1}{2}$ grains, was given every four hours. The temperature fell to normal in eight days. The child was very comfortable, and up to the time of writing the dressing has not been changed. Examination of the pus showed the presence of *Staph. aureus*. Blood culture was negative. This case was not quite so severe as the others, and has made exceptionally good progress.

Commentary

These case notes have been made as brief as is possible, and any discussion of local dressings, splintage, and sun exposure has been omitted.

As I have pointed out, the series is a short one, and it may be argued that similar recoveries might have been obtained by treatment other than that adopted, but I feel strongly that all these cases have done exceptionally well, particularly Cases I and II, which seemed absolutely hopeless. All of them were definitely of the really severe septic osteomyelitis, and not of the milder type sometimes seen.

PELVIC HYDATID CYSTS AND OBSTRUCTED LABOUR

BY

MOSTYN P. EMBREY, B.Sc., M.B., B.Ch., M.R.C.S.

Ewen Maclean Research Scholar and Second Assistant,
Department of Obstetrics and Gynaecology,
Welsh National School of Medicine

Perusal of the literature leaves little doubt that, in this country at least, obstructed labour is only rarely caused by a hydatid cyst. Such a case recently seen in the practice of the maternity department of the Cardiff Royal Infirmary prompted me to consult the hospital records. They revealed a similar case fifteen years ago, and so this opportunity is taken of describing both cases.

Case I

A 5-gravida aged 33 was admitted on October 24, 1923, having been referred by Dr. Burns of Abertillery. She had previously had four living children—three *per vias naturales* and one by Caesarean section—and no miscarriages. The patient had been unwell during the early months of pregnancy and a hydatid cyst had been removed from the anterior aspect of the uterus at the fifth month.

Examination revealed a full-term pregnancy, labour being obstructed by a large mass in the pouch of Douglas. Classical Caesarean section was performed and a full-term living child weighing 6 lb. was delivered. The uterine incision was brought together with mattress sutures and the abdomen explored. The uterus, especially its right lower aspect, was studded with small tubercle-like bodies. There was a large retro-uterine fluctuant mass in the pelvis, with a number of hard white masses resembling caseous glands attached to the omentum. On manipulation the pelvic mass ruptured, and what appeared to be pus and masses of endocyst were extruded. A large number of cysts of all sizes were attached to the omentum and peritoneal surfaces, and were removed. Further exploration revealed a hard calcareous mass attached to the under surface of the liver, but whether primarily there or in adherent omentum could not be ascertained. Removal of the mass was

considered inadvisable. Subtotal hysterectomy was then performed, with removal of the left appendages and what remained of the right, and the abdomen was closed.

Progress was fairly satisfactory until the twenty-fourth day after operation, when the patient suddenly collapsed and died, apparently from a pulmonary embolism. Permission for a post-mortem examination was not obtained.

Case II

An 8-gravida aged 35 was referred to the Infirmary by Dr. Roberts of Barry on February 5, 1938, as a case of labour obstructed by a pelvic tumour. She had had three miscarriages followed by four normal confinements, the last being two and a half years previously.

At the time of admission the membranes had been ruptured thirty-five hours and labour had been in progress sixteen hours. Abdominal examination revealed a full-term pregnancy, the foetus presenting by the breech in the left sacro-anterior position and the foetal heart rate being 138 per minute. Contractions were recurring every five minutes. On vaginal examination the cervix was found to be half dilated, with the breech presenting high up. There was a firm irregular mass in the pouch of Douglas about the size of a coconut which did not appear to be attached to the uterus and which was obviously obstructing labour. A tentative diagnosis of impacted ovarian cyst was made.

Classical Caesarean section was performed and the patient delivered of a full-term living child weighing 6½ lb. The uterine wound was closed and the abdomen explored. There were multiple cysts in the abdomen—eight to ten in number. The ovaries were not involved. One cyst attached to the upper surface of the bladder, and a second attached to the descending colon by adhesions, were removed for microscopical examination. Other cysts were intimately attached to the colon and mesocolon, and varied from the size of a walnut to that of a coconut. One such cyst was impacted in the pouch of Douglas, obstructing labour. As removal of all the cysts would have meant considerable dissection and have taken much time, it was thought advisable to close the abdomen. Convalescence was uneventful, and the patient was discharged twenty-five days after operation.

The diagnosis of hydatid cyst was confirmed microscopically. A blood count revealed an eosinophilia of 5 per cent, and the Casoni reaction was positive. The patient had always enjoyed good health, and inquiry failed to elicit any previous, family, or social history suggesting hydatid disease.

Pathological and Clinical Considerations

The two cases described were almost certainly examples of secondary echinococcosis. They serve to emphasize certain pathological and clinical aspects of hydatid disease which are as yet not sufficiently appreciated and which may be briefly outlined.

Following ingestion of the ovum the hexacanth embryo hatches in the upper part of the alimentary canal and, travelling via the radicles of the portal vein, lodges as a rule in the liver. Here, as a result of growth changes which need not be detailed, the typical univesicular hydatid cyst is formed, consisting of an outer ectocyst, or laminated layer, and an inner endocyst, or germinal layer containing specific fluid in which float the reproductive elements—the whole surrounded by a fibrous adventitia derived from the host. The scolices grow inside specialized brood capsules, and with their formation the cyst may be said to be fully developed. Such a cyst is typically found in a child or young adult; for in the majority of cases infestation takes place in childhood, so that the cyst is nearly as old as the host.

In nearly all instances it is the onset of complications that determines the first clinical manifestation of hydatid disease. In the great majority of cases these complications

depend on the previous escape of fluid from the cyst—varying from a slight leak to a frank rupture—and commonly occur after the third decade of life.

Rupture of the cyst may take place into the subcutaneous or muscular tissues, into the bile ducts, bronchi, alimentary canal, or urinary tract; into a serous cavity such as the peritoneum, pleura, or pericardium; or into the chambers of the heart or large veins. Each presents its own characteristics, but according to Dew (1930-1) the sequelae may be grouped as follows:

General—applicable to all types:

1. Immediate: Anaphylaxis.
2. Delayed: Secondary echinococcosis.

Special—applicable particularly to rupture into a natural channel:

1. Immediate: Mechanical effects.
2. Delayed: Suppuration in the cyst.

Of these sequelae it is only necessary to consider briefly anaphylaxis and secondary echinococcosis.

ANAPHYLAXIS

The appearance of anaphylactic phenomena following rupture or puncture of a hydatid cyst has been noted many times. The most common of these manifestations are urticaria, dyspnoea, cyanosis, abdominal pain, vomiting, syncope, and delirium. The severity of the anaphylactic reaction varies within wide limits, but it is probable that were more accurate histories obtained clinical evidence of anaphylaxis would often be revealed.

SECONDARY ECHINOCOCCOSIS

For many years the majority of clinicians regarded multiple cysts as evidence of multiple primary infestations, but it is now known that they are nearly always manifestations of secondary echinococcosis following rupture of the primary cyst and the implantation of daughter cysts or scolices. There are many clinical examples of this phenomenon, but only two—the localized and intraperitoneal types—need be mentioned.

Slight leakage of fluid from a single cyst, following puncture or mild trauma, may give rise to the formation of multiple secondary cysts within the confines of the adventitia, and is one of the commonest types of reactive daughter-cyst formation. Dew is of the opinion that probably all cases of endogenous daughter-cyst formation are best regarded as a special type of localized secondary echinococcosis.

Multiple secondary cysts of the peritoneal cavity are relatively common, and are always due to leakage of reproductive elements from a primary cyst of the liver or, rarely, the spleen or kidney. These secondary cysts become completely surrounded by the peritoneal epithelium, so as often to give the impression that they have developed in an extraperitoneal situation. They are of slow growth, with a latent period of from five to ten years before they produce symptoms. They are prone to further rupture, with the production of more cysts, so that ultimately the peritoneal cavity may be almost filled with hydatid cysts in all stages of development. The original primary cyst may be completely evacuated, so that after a lapse of years it may be exceedingly difficult to detect the primary site. More commonly, however, the rupture becomes sealed off by adhesions, and the residual germinal elements produce multiple daughter cysts—one type of localized secondary echinococcosis.

The multiple intraperitoneal cysts present in each of the cases described were undoubtedly produced by rupture of a primary hydatid cyst as outlined above. In Case I

the calcareous mass attached to the under surface of the liver would appear to have been the remains of the primary cyst. In Case II the primary cyst was not located. In neither case was a history suggestive of anaphylaxis obtained, so that the time of rupture of the primary cyst cannot be known; but it is likely that in each case multiple cysts had been present and unsuspected in the peritoneal cavity for several years.

In Case I the first manifestation of hydatid disease appears to have been in the earlier months of the pregnancy, when the patient began to feel unwell. Presumably in consequence of an examination laparotomy was performed and a hydatid cyst removed from the anterior part of the uterus. In Case II hydatid disease was not suspected until the occurrence of an obstructed labour due to a cyst being impacted in the pouch of Douglas. It is noteworthy that in both cases, although hydatid disease had probably been present for many years, it was not discovered until the fourth decade of life, and then only on account of an associated pregnancy.

Literature

References in the literature to the ubiquitous hydatid cyst in relation to pregnancy and parturition are few. Franta (1902) collected all the recorded cases and dealt with them in three papers. The first was concerned with dystocia due to hydatid cysts in the pelvis, and recorded thirty-six cases. The second contained an account of twenty-two cases in which operation for removal of the cyst was performed in pregnancy. The third dealt with the influence of pregnancy, labour, and the puerperium on hydatid cysts. I am aware of only four recorded instances in this country. Gemmell (1899) described a case of hydatid cyst in the omentum obstructing labour which was treated by abdominal section and removal in the puerperium. Blacker (1903) published a case of hydatid cysts complicating pregnancy in which Porro-Caesarean section was performed. Andrews (1903) also described a case in which pregnancy was complicated by the presence of a hydatid cyst in the pelvis. The remaining case is that of Bell (1925), whose patient had an obstructed labour necessitating craniotomy, the cyst subsequently being removed during a second pregnancy.

Summary

1. Two cases of obstructed labour due to a hydatid cyst are described because of their comparative rarity.
2. Both cases were examples of secondary echinococcosis with multiple cysts in the peritoneal cavity.
3. In neither case was there a history of anaphylactic manifestations such as frequently accompany rupture of the primary cyst.
4. Although hydatid disease had probably been present for several years, it had not been suspected. In the first case it was discovered at the fifth month of pregnancy, and in the second during labour.

I wish to express my thanks to Sir Ewen Maclean and Dr. M. D. Arwyn Evans for permission to publish these cases.

EPIDEMIC MYALGIA

FIVE CASES IN ONE HOUSEHOLD

BY

C. R. G. HOWARD, M.B., Ch.B.

Department of Medicine, University of Bristol

The following account of an outbreak of epidemic myalgia may be of some value, as it provides a possible differential diagnosis in cases of appendicitis, pleurisy, cholecystitis, and muscular rheumatism.

Survey of Literature

Daae (1874) in Norway is first credited with describing the disease, which, he says, is distinguished by pain in the chest and back, febrile disturbance, and relapses. Gradually it became recognized as a clinical entity, and by 1888 the name "devil's grip" had been associated with it in America. From this time it attracted little attention until 1930, when Sylvest (1930, 1931) gave a full account of an epidemic which occurred on the island of Bornholm, in which 10 per cent. of the population were attacked. He described the onset as sudden, with pain in the hypogastrium and nausea, the pain shifting to the chest and shoulders after a few hours. These symptoms are associated with fever, from 99° to 105° F., and the attack lasts a few days. Relapses are frequent. Sylvest noticed a seasonal incidence in summer and early autumn. The sexes are equally affected, and, although no age is exempt, most cases occur between the ages of 5 and 15. There appeared to be an incubation period of two to four days, and examination of the blood showed an eosinophilia.

Since 1930 there have been a few reports in the literature. Rector (1935) records nineteen cases in which the patient was under 8 years old, and he suggests the use of quinine sulphate in cases that do not clear up quickly. Smith (1937) gives an account of an epidemic at Rugby School, in which there were myalgic pains, chiefly in the back of the neck.

In 1934 the disease received more attention owing to several outbreaks in American towns. MacDonald, Howell, and Cooper (1937) investigated an outbreak in Cincinnati; clinically they found the same picture as did Sylvest, but there were no patients over 15 years of age. They point out that constipation was frequent and relapses after a few days were common features. These workers found no eosinophilia, but some of the patients had a leucopenia. Bacteriological investigations of the cerebrospinal fluid were negative, as also were blood cultures. The Wassermann reaction was negative in all cases. Cooper and Keller (1937) tried to find a specific organism in washings of the throat and nose, but the only constant growth was a small colony type of *Streptococcus viridans*, to which they attached little importance. Later work with animals suggested a filterable virus as the cause, with a possible incubation period of eight to ten days. F. Wolter (1937), investigating a series of outbreaks in Germany, adds the fact that the urine is usually very dark in colour, and this, he suggests, is due to the presence of creatinine, which he attributes to the changes in the muscles. He discusses the connexion between epidemic myalgia and epidemic poliomyelitis, and points out that there is a similar seasonal and climatic incidence.

Case Records

Case 1.—A man aged 26 first complained of epigastric pain, made worse by meals. The following afternoon the pain became very acute and was localized to the right costal margin; there were no clinical signs of pleurisy and a radiograph of the chest was normal. During the next two days the pain in the chest became much less severe, but it was made worse by deep breathing or laughing. Tenesmus was present. On the fifth day there was a relapse, with headache, sweating, and a temperature of 101° F. After 30 grains of aspirin had been taken there was a profuse perspiration followed by considerable improvement. During the next three days the pain in the lower part of the chest became less severe and was more generalized over the back and shoulders.

Case 2.—A woman aged 27 complained of vague abdominal pain with nausea; the next morning the abdominal pain was worse and tenesmus was pronounced; in the afternoon there was a sudden onset of pain in the right costal margin, aggravated by coughing or laughing. On the third day she felt better, but had a relapse in the afternoon, and complained of feeling hot and exhausted. The temperature was not taken. During the next three days the pain became less, and finally disappeared after a treatment with an infra-red lamp.

These patients did not go to bed.

Case 3.—A woman aged 26 complained of a sudden onset of pain in the abdomen and general malaise eight days after exposure to Cases 1 and 2. Her temperature was 103° F., and she went to bed. The next day the pain was localized to the right costal margin and was made worse by coughing or deep breathing. The morning temperature was 101° F., and the evening 102° F. A blood film was taken which proved normal. Tenesmus was present. On the third day she felt better; her temperature was normal and she got up. The following day there was a mild relapse, the patient feeling hot and sweating, but she managed to undertake a railway journey.

Case 4.—A baby aged 15 months had a general upset, being off her food and appearing to have pain in the abdomen, especially when crying; she was sick twice. The following day she was well but fretful. On the third day she had a relapse, the temperature being 102° F., but there were no localizing symptoms. During the next few days the child was off its food but was otherwise well. The motions were normal.

Case 5.—A female aged 17, nurse to Case 4, developed abdominal pain, with general malaise and a temperature of 99° F., ten days after Case 4 had recovered. The next day the pain was localized to the right side of the chest, where it persisted for two or three days. There was no relapse. This was a very mild attack, if one at all.

Commentary

These cases thus closely followed the clinical picture described by Sylvest, the main features being a sudden onset with abdominal pain and malaise, the pain moving to the chest, particularly the right costal margin (Cases 1, 2, and 3), on the second day, later diffusing all over the chest and shoulder. Pyrexia varied from 99° to 103° F., and tenesmus was present in three cases. A relapse on the third, fourth, or fifth day was noticed in four cases. Cases 3 and 5 appeared to have incubation periods of eight and ten days respectively.

The chief disabilities are intermittent attacks of malaise for about a week, combined with the inability to laugh or take a deep breath without excruciating pain in the chest, also the frustration, in spite of a strong urge, of being unable to defaecate satisfactorily.

It is interesting to note that at about the same time as the above cases occurred there were admitted to the local hospital more cases than usual, perhaps, of appendicitis that never came to operation. Unfortunately these were not investigated from the point of view of myalgia.

Summary

A brief review of the literature of epidemic myalgia is presented, together with an account of five cases occurring in one household.

Clinical Memoranda

Domiciliary Emergency Treatment of Eclampsia

There is no gainsaying the fact that domiciliary treatment of persons acutely ill of obstetrical complications is the correct one, not only in the homes of the well-to-do but also in the overcrowded homes of the poor. Hospitals have their place in the treatment of disease, but a review of the table below proves beyond doubt that the emergency treatment of eclampsia at home is pre-eminently the best line.

Comparative Statement of Cases of Eclampsia Treated from 1933 to 1937 in Hospital and by Domiciliary Emergency Measures

| | 1933 | 1934 | 1935 | 1936 | 1937 | | Totals |
|---|-------|-------|-------|-------|-------|---|--------|
| Total admissions to hospital .. | 1,416 | 1,649 | 1,759 | 1,729 | 1,780 | | 8,333 |
| Cases of eclampsia occurring in hospital or admitted after onset .. | 13 | 13 | 17 | 26 | 17 | Incidence 1.03% Average death rate 11.6% | 86 |
| Deaths .. | 2 | 2 | 1 | 5 | 0 | | 10 |
| Emergency team: Cases treated in own home | 4 | 10 | 13 | 5 | 11 | | 43 |
| Deaths .. | 0 | 0* | 0 | 0 | 0 | | 0 |
| Hospital and home cases combined .. | 17 | 23 | 30 | 31 | 28 | | 129 |
| Deaths .. | 2 | 2 | 1 | 5 | 0 | Average death rate 7.7% | 10 |

* Of the patients attended in their own homes during 1934 one was dead before the arrival of the emergency team.

As our experience increases the pitfalls become apparent: one that I have observed is where there is such a pronounced elevation of the blood pressure in a case of pre-eclamptic toxæmia that even the excitement attending transport and admission to hospital causes the patient to develop an eclamptic seizure, the prognosis of which it is difficult to forecast.

During the past five years 8,333 cases have been admitted to this institution, and eighty-six have suffered from eclampsia either before or after admission, with a mortality rate of 11.6 per cent.; whereas during the same period forty-three cases were treated in their own

homes without any mortality. During the period under review it has been left to the general practitioner in charge of the case to decide whether the patient should be admitted to hospital or not, and, generally speaking, those treated in their own homes have been seriously ill with advanced symptoms of eclampsia. One would therefore expect that the death rate of these cases would be considerably higher than that in the hospital, but that is not so. Previous to the advent of domiciliary emergency treatment the mortality rate from eclampsia was in the neighbourhood of 20 per cent.

TREATMENT

Our treatment of eclampsia is simple: a darkened room, freedom from noise, careful nursing, an initial sedative dose of morphine hydrochloride 1/6 to 1/4 grain, varying according to the severity of the attack, followed by doses of chloral and bromide, 20 grains of each, hourly until fits are controlled. No fluids are allowed during the unconscious state, and only a limited amount after the patient becomes conscious. Mist. senna co. 3 to 4 oz. orally and a magnesium sulphate enema are given if the bowels are obstinate. Lumbar puncture is performed under light anaesthesia, which is again resorted to if fits supervene.

H. J. THOMSON, M.D., M.C.O.G.,

Physician Superintendent, County Maternity
Hospital.

Bellshill, Lanark.

Locked Twins

The following record of a case of locked twins with survival of the second twin seems worthy of publication.

A primipara aged 24 was admitted to hospital on August 18 as a case of obstructed labour. On admission a foetus was showing between the legs, having been born as far as the head in a breech presentation; it was dead. The history was that labour had started two days previously, was about six weeks premature, and the membranes had ruptured twelve hours before admission.

The woman was in good condition, and abdominal examination revealed twins, the second presented as a vertex. The patient was immediately given a general anaesthetic, and vaginal examination showed that the twins were locked, the head of the first, which was above the brim, being held up by the head of the second, which was in the pelvis. The second head was pushed up quite easily and the dead foetus removed. An internal version was then carried out upon the remaining twin, and it was extracted readily by the breech. It was found to be alive.

The woman had an uncomplicated convalescence, and the second twin survived after a severe attack of melaena neonatorum, which was treated by intramuscular injections of the mother's whole blood and haemoplastin. The twins weighed 4 lb. and 3 lb. 12 oz. respectively, the mother's pelvic measurements being 11 by 12 by 8 inches.

COMMENTARY

The interest of this case lies, first, in the rarity not only of locked twins but especially locking of the two heads (Queen Charlotte's *Obstetrics* stating that no case has been seen in the experience of that institution), and, secondly, in the survival of the second twin.

The fact that several cases have been recorded in the last few weeks shows that the condition is not as uncommon as is thought.

I wish to thank Mr. H. I. Deitch, medical superintendent, General Hospital, Halifax, for permission to publish this case.

J. J. RUSSELL, M.B.,
Resident Obstetrical Officer,
Halifax General Hospital.

Reviews

PROBLEMS OF POPULATION

Population: To-Day's Question. By G. F. McCleary. (Pp. 222; frontispiece. 6s. net.) London: George Allen and Unwin, 1938.

In more than one previous book Dr. G. F. McCleary has demonstrated his command of a lucid and agreeable literary style and his ability to present the really important part of a difficult scientific argument without using technical terms. His latest book, *Population*, is worthy of the reputation he has gained. It would not be difficult for a less skilful writer than Dr. McCleary to make a sensational story of the historical facts or a thrilling forecast of the future. But to make statistically clear why (1) an actual increase of population may be strong evidence that population will shortly decline enormously, (2) a decreasing population involves increasing unemployment, needs something more than literary facility. Dr. McCleary succeeds here, partly by a careful choice of arithmetical methods, partly by the use of judicious analogy. To the "common-sense" objection that population is in fact still increasing he retorts that no wise business man would disregard an unfavourable report of his accountant merely because his takings substantially exceeded his expenses. As Dr. McCleary succeeds in the most difficult part of his undertaking, it is not surprising that, in his exposition of opinions respecting the reasons for a decrease of population and of attempts to check the decrease, he is candid and instructive. His observations on the recent demographic history of Italy and Germany are particularly valuable.

Broadly speaking, measures to encourage an increase of population are of the following kind. The statesman endeavours by methods of differential taxation or occupational preference to reduce the social and economic disadvantage which, under modern conditions, parents with many children suffer. But as the positive effects of these measures never go further than to reduce the disadvantage it is necessary either to persuade the deliberately infertile that the measures are more effective than they really are or to change their emotional outlook on the facts of life. In Germany and Italy both plans have been in operation: in Italy for more than a decade; in Germany since 1933. In Italy the results have been trivial. "Signor Mussolini has done many wonderful things, but he has not yet succeeded in inducing his countrymen to produce more babies." Herr Hitler has been relatively more successful, but it is too early to say more. How far the relative success of the German campaign is due to (a) better planning of the financial aids or (b) a greater capacity of Germans to believe what they are told and act upon instructions is hard to say. Indeed, to form an opinion requires much more intimate knowledge of financial and psychological questions than most readers can have. Dr. Burgdörfer thinks a new confidence in the future is an important factor. If the German nation as a whole really possesses that confidence its spiritual condition is unlike that of some other populous nations. Whether recent events or the comments of public men of all shades of opinion upon those events are likely to foster confidence in the future of the British people is a question which Dr. McCleary naturally does not discuss. All will agree with one of the concluding sentences of his book—"Of one thing, however, we may reasonably be sure: the formulation of an effective population policy will be no

easy task." Indeed we might phrase this more harshly, and say that until statesmen have learned how to utilize and protect the population in being they need not spend time in preparation to stave off a natural decline of population.

HAEMATOLOGICAL TECHNIQUE

Laboratory Manual of Hematologic Technic, including Interpretations. By Regena Cook Beck, M.A., M.D. With a Foreword by Frank W. Konzelmann, M.D. (Pp. 389; 79 figures, 72 tables. 18s. net.) London: W. B. Saunders. 1938.

The students of laboratory technique at the School of Medical Technology, Richmond, Va., will find the manual of haematological technique by Dr. R. C. Beck a valuable if not indispensable guide in their work. Laboratory technicians have a special professional status in the United States which has not as yet developed to the same extent in this country; they constitute an important group of workers almost exclusively women. This manual is a compilation of laboratory methods collected from various sources, many of which are unfamiliar to workers in this country, but are in routine application at Dr. Beck's institution, where they seem to fulfil the same useful purposes as those of all carefully planned methods. With the modern zeal for attaining accurate and reliable results laboratory technique has attained almost universally to so high a standard that there is little opportunity for selection, and every laboratory may safely adopt the methods best fitted to its equipment.

The methods chosen for this manual are clearly and simply described and comparatively free from the distraction of references and names of authorities. It is surely an inaccurate or biased claim of Professor F. W. Konzelmann in his foreword that "at the time of this writing there is no other single volume where so much information on the subject of procedure in haematology is contained between two covers." The book is, of course, American in style, but is commendably free from arresting words and expressions.

CONTROL OF VENEREAL DISEASE

Syphilis, Gonorrhoea and the Public Health. By Nels A. Nelson, B.S., M.D., and Gladys L. Crain. (Pp. 359; 15 tables. 12s. 6d. net.) New York: The Macmillan Company. 1938.

In few countries is the problem of venereal disease more difficult of solution than in the United States of America, and those who are interested may with advantage study *Syphilis, Gonorrhoea and the Public Health*. This book is divided into two main sections, the first dealing with the clinical and pathological side of venereal disease, and the second with its control. The former is excellent, giving a simple straightforward account of the history, diagnosis, and treatment of gonorrhoea and syphilis which is intelligible to any layman, and which might be read with profit by many doctors: though this is compressed into less than 150 pages there appear to be no important omissions and little to criticize. Perhaps to say that "if the red cells remain red the test [Wassermann] is positive," and "if the red cells are decolorized the test is negative," may hardly convey the true facts very accurately, while the diagram of gonococci does not look very much like the real thing; but these are minor shortcomings in a really admirable section.

The second section of the book deals with the incidence, prevalence, and control of venereal disease, and may well

prove an eye-opener to the uninitiated layman, for the general public has very little idea of the extent to which venereal disease has permeated all ranks of society. A control programme should include both syphilis and gonorrhoea; it concerns health departments, the medical profession, and the social worker. Case finding, case control, treatment, and diagnostic facilities all have to be considered, and no less important is the education not only of the patient but of the doctor, the nurse, and the general public. It remains open to question whether compulsion in any form is more efficient than persuasion, but what is clear is that, so far as America is concerned, more money, more V.D. specialists, and more free treatment are required before there can be any hope of reducing materially the incidence of venereal disease. Conditions are far more difficult in the U.S.A. than in most countries owing to the number of component States and the different races involved, including, as these latter do, a large coloured element.

This book should appeal more particularly to the medical officer of health and to the social service worker; to the former it should make it clear that venereal disease cannot be controlled by the same methods as are other communicable diseases, and the latter will realize the importance of finding and holding cases and contacts. Now that the subject of venereal disease is no longer barred from ordinary conversation or by the Press, and now that the public conscience is being awakened to the seriousness of the problem, there is hope that much progress in its control will be made.

MATERIA MEDICA

Traité de Pharmacie Chimique. Volume I. Chimie Minérale et Chimie Organique (Série Aeyclique). Volume II. Chimie Organique. (Two books.) By P. Lebeau and G. Courtois. Second edition. (Pp. 1,206 and 2,128; Vol. I, paper cover, 250 fr.; cloth, 280 fr. Vol. II, paper cover, 410 fr.; cloth, 460 fr.) Paris: Masson et Cie. 1938.

This is a comprehensive work on all kinds of therapeutic agents. It deals more especially with their chemical characters, properties, and relationships, but also includes information on matters of importance affecting their use in medicine. The plan of treatment is not dissimilar to that of works of a kindred nature, of which the *British Pharmaceutical Codex* is an example. Under the name of every substance, used as a title, there appears a descriptive monograph reciting generally the synonyms by which it is otherwise known, information relating to its source, the mode of preparation, the chemical formula and chemical properties, tests of purity, method of assay, the physiological action, therapeutic use, and the medicinal dose. Other matters of information are also interpolated whenever they are of material importance; such, for example, as the pharmacopoeias of other nations in which the substance is official. It does not describe crude vegetable drugs but only the active principles obtained from them, nor does it touch upon galenical products or formularies of the nature of prescriptions.

The monographs are arranged in sections corresponding with a chemical plan of grouping, one group comprising glucosides, another comprising alkaloids, and a third proteins. There is an introductory article to each sectional group giving a historical and general dissertation on the members of the series. Thus the leading article on tannins, which is treated as a subsection of the glucosides, recites the different varieties of substances distinguishable as members of the group, describes their relation to each

other, and gives an account of the more important researches by which their individual constitution has been established. This plan of treatment is well exemplified by the article on glycerophosphoric acid, which recites the first observation by Pelouze in 1845 that glycerin reacts with phosphoric anhydride with the disengagement of heat, and refers further to the work of Goble, who isolated the substance from yolk of egg. Then follow descriptive references to the observations of successive authors who elucidated the relationships of the alpha and beta forms of the substance to each other: all this is described in illuminating detail with chemical formulae and equations. Then follow monographs on the several salts of glycerophosphoric acid. A similar discussion appears under the title of "radio-activity," followed by monographs on compounds of uranium, thorium, and others. The technology of alcohol is treated very fully. Its manufacture by fermentation and by chemical synthesis is described in detail, as well as various methods of dehydration in use for the production of absolute alcohol.

Perhaps the most outstanding feature of the work is its encyclopaedic character. Whatever therapeutic agent may be the subject of reference, whether it be the most recent product of synthetic chemistry or a well-nigh forgotten representative of bygone medical practice, an account of it will almost certainly be found. Organic substances prepared by chemical synthesis are treated in the same thorough manner to which allusion has been made above. Lebeau and Courtois's treatise is indeed *sui generis*; it cannot fail to prove valuable to anyone who is interested in the chemistry of therapeutic remedies.

A MEDICAL MISSIONARY IN THE SUDAN

The Doctor Comes to Lui. A Story of Beginnings in the Sudan. By Eileen Fraser. With an Introduction by the Bishop in Egypt and the Sudan. (Pp. 71; 26 illustrations. 2 maps. 1s.) London: Church Missionary Society. 1938.

In this little book Mrs. Eileen Fraser tells the story of a medical missionary and his wife in the Sudan. Lui, formerly Yilu, lies in the centre of the Moru country, virgin territory of Central Africa, a thousand miles south of Khartoum and 120 miles west of the White Nile. Thither Mrs. Fraser and her husband, the late Dr. Kenneth Fraser, set out in the year 1920 to devote themselves to the task of bringing spiritual and physical comfort to the Moru people. With wattle and daub they built a house for themselves, a hospital, and a school on a site which had served for many years as the headquarters of a notorious slave trader. From these small beginnings an organization was built up, extending eventually to sixteen different centres, in which 27,423 cases were treated during the year 1937. Dr. Fraser, who died in 1935, proved himself not only a devoted doctor and evangelist but also a born organizer. Following a policy of decentralization he trained native helpers and established them in outlying stations; thereby enormously increasing the scope and value of his work.

Written in modest and straightforward style, Mrs. Fraser's book makes light of the immense difficulties to be overcome in this remote region, infested with wild animals, and with a backward population riddled with disease. The work of these two pioneers is the more admirable in view of the fact that Dr. Fraser was already in the forties when he first went to Moru. The value of the book, which may be especially commended to medical men, is enhanced by relevant maps and a large number of really good photographs. It is an excellent shilling's worth.

Notes on Books

A new edition has been published by H. K. Lewis and Co., Ltd., at 12s. 6d. of Mr. EUGENE WOLFF'S *Anatomy for Artists*, illustrated from original drawings by Mr. GEORGE CHARLTON, who has added a number of new figures. The trunk and limbs are shown in positions other than those necessarily used in descriptive anatomy, and the importance of the bony points lying under the skin is again emphasized. As we noted when reviewing the second edition, stress is rightly laid by Mr. Wolff on a thorough knowledge of the skeleton as an indispensable basis for the understanding of form and function. Mr. Charlton's drawings are clear and vigorous, and he brings out very well the distinction between the fleshy and the tendinous portions of muscles. New figures illustrate the importance of the skull in the formation of the face, show the position of the eyeball in its socket, and demonstrate the parts played by the thyroid cartilage and thyroid gland in the surface form of the neck. The production of this book reflects credit on author, artist, and publisher.

Erleiden des Auges, edited by Dr. ARTHUR GÜTT, and published at Leipzig by Georg Thieme at the price of RM. 26, is a compilation by many contributors, and covers very much the same field as the larger and individual monographs on hereditary disease of the eye by Waardenburg and by Franceschetti. A certain amount of more recent literature is noted in the present volume, which, like the *Handbuch der Erbkrankheiten*, of which it is part, is essentially utilitarian rather than academic, and aims at giving the necessary scientific background for the application of the German eugenics laws. Much of the space is devoted to medico-legal discussions which are only of indirect interest to the English reader. So far as the academic matter is concerned, some sections, notably that of Bücklers, are comprehensive and valuable; others are distinctly sketchy. The book is profusely illustrated, and some of the bibliographies are useful.

Preliminary Studies of a Vaudeville Telepathist. Bulletin III. by S. G. SOAL, M.A., B.Sc., is published by the University of London Council for Psychical Investigation at 5s. This careful study shows that "Marion" discovers hidden objects by watching minute movements of members of the audience who know where the object is hidden, and recognizes cards if he has handled them by his very keen tactual sense, but that he cannot prove any capacity for true telepathy.

Preparations and Appliances

A "PIN" EYE-DROPPER

Mr. N. BISHOP HARMAN, F.R.C.S. (London, W.1), writes:

Oily preparations of alkaloids for the treatment of eye diseases are in many cases preferable to watery solutions.

Oily preparations keep better, and in some cases they are more effective—for example, eserine in castor oil in the palliative treatment of chronic glaucoma, or homatropine in refraction work. Oily preparations are perhaps less used than they might be owing to their messiness. This arises from too much being put into the eye by using a glass rod or dropper. The "pin" eye-dropper meets this difficulty. It is an ordinary domestic pin fixed in a suitable handle, and the whole chromium plated. If the head only of the pin be dipped into the oil it will lift a globule of the right volume, which by a touch on the mucosa of the lower lid is transferred to the eye. The dropper can be boiled. It is made by Messrs. W. Martindale of New Cavendish Street, London, W.1.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 10 1938

HEALTH AND AGRICULTURE

The pre-eminent influence of food in determining man's general physical endowment, powers of endurance, and resistance to disease gives to efficient agriculture a foremost place among public health services. It was inevitable that those whose business lay in the investigation of the relations of food to health and disease and of the health-promoting properties of certain natural foodstuffs should have come to regard the proper care and cultivation of the soil and the economic production of health-giving foodstuffs as a most important public health measure. But the attempt to induce the public, the Government, and the farmer himself so to regard agriculture—and in consequence of this regard to establish it as part of a comprehensive public health policy—has been the business of others. Last year the League of Nations published the final report of the Mixed Committee, presided over by Viscount Astor, on *The Relation of Nutrition to Health, Agriculture, and Economic Policy*: a report replete with information on this highly important matter. In it there occurs a passage which cannot be too often repeated:

"Millions of people in all parts of the globe are either suffering from inadequate physical development or from disease due to malnutrition or are living in a state of sub-normal health which could be improved if they consumed more or different food. That this situation can exist in a world in which agricultural resources are so abundant and the arts of agriculture have been so improved that supply frequently tends to outstrip effective demand remains an outstanding challenge to constructive statesmanship and international co-operation."

Now there appears another report of an inquiry on British agriculture¹ organized by Lord Astor and Mr. Seeborn Rowntree which is of profound interest from the point of view of national health in this country. They set themselves the task of answering these questions: What can British agriculture produce most effectively and most economically, having regard to our soil, climate, and economic conditions? What does the consumer need most from British agriculture? They came to the conclusion that the best interests of the agricultural producer and of the consuming public coincide. The new knowledge of nutrition

emphasizes the importance to human welfare of the consumption of adequate quantities of the "health-protective" foods as distinct from the energy-bearing foods. The main foods falling into this category are milk (pre-eminently), fresh fruit, vegetables, and eggs. And for the production of these Britain is especially fitted by natural conditions; and can be still better fitted, in regard to milk, by the application of the new knowledge now available for improving grassland cultivation. Moreover, British farming enjoys a natural protection in these perishable products through proximity to the market. "We should therefore aim at effecting a marriage of agriculture and nutrition by subsidizing the production of the protective foods rather than in giving subsidies to the production of energy-bearing foods. This policy would not only further the interests of agriculture in Britain but would also have an inestimable value on the standards of national health."

In practice, as the authors of the report point out, the central feature of a constructive nutritional policy must be the promotion of the consumption of milk. The potentialities of enlarging agricultural production by a successful policy of stimulating milk consumption are very large. The present average *per capita* consumption of milk by the British public is extremely low. If it were increased by one-third of a pint a day it would still be far below the level which is desirable on nutritional grounds; yet such an increase would entail an expansion of our natural milk output of no less than 65 per cent. At the present rate of productivity this would require the maintenance of 2½ million more cows. The authors of the report urge that the constitution of the marketing boards which administer the various statutory marketing schemes should be transformed. They recommend that these boards should be appointed by the appropriate departments of State to represent the public interest: a reform which, in their judgment, is essential if agricultural marketing is to evolve on satisfactory lines. "It would be far easier to develop constructive schemes for stimulating an increased consumption of milk and other protective foods, or for improving the system of retail distribution, if the powers of the marketing boards were in the hands of bodies representative of the public interest." With the other proposals here put forward we are not immediately concerned. State ownership of certain lands, land improvement commissions, measures for increasing farming efficiency, educational and advisory services, more energetic attempts to eradicate animal disease, improving the quality of the product in many branches of farming, measures to maintain and improve the fertility of the soil, improvements in conditions of

¹ *British Agriculture: The Principles of Future Policy*. A report of an inquiry organized by Viscount Astor and B. Seeborn Rowntree. (Longmans, Green and Co. 15s.)

life of agricultural workers—all these are among them. What concerns the medical profession as guardian of the public health is that agriculture should be given its rightful place among the public health services, and that the agricultural policy of the future should be part and parcel of a national policy of nutrition. The report by Lord Astor and Mr. Seebohm Rowntree will, by developing public opinion, contribute greatly to the attainment of this much-to-be-desired end.

RADIUM BEAM THERAPY

Of the many special reports which have from time to time been issued under the auspices of the Medical Research Council few have been so valuable and important as that on *Radium Beam Therapy*,¹ which has just appeared. As this method of treating cancer had already been successfully used in France, Belgium, the United States, and especially in Sweden, it was decided in 1933 to undertake systematic investigations in this country, and the Radium Beam Therapy Research was inaugurated. From the first it was decided that physical investigations must precede any clinical work, especially as regards the protection of patients and staff, as well as of other occupants of the building in which the work was carried out. Another direction in which exhaustive physical research was imperative was the effective and safe distribution of the dosage. In every form of radium therapy any errors, in either the quantity or quality of the radiations used, are serious and often irreparable; with the large masses of radium employed in beam therapy they are more than likely to be fatal. The clinical part of the work was put in charge of Miss Constance Wood, Mr. L. G. Grimmett, and Mr. T. A. Green, and it is a magnificent tribute to their knowledge and skill that, although the inquiry extended over four years and included the treatment of 366 patients, in no instance was there the slightest trace of accidental damage from radiation—either to the patients or to the staff. The radium employed was at first a unit of 5 grammes, but a further unit of 5 grammes was added subsequently. The greatest care had obviously to be taken in moving these large amounts, and a pneumatic transference device enabled the radium to be taken from the safe where it was kept and placed in the required position without any handling or exposure of the operators. The exact placing of the patient and the adjustment of the apparatus were all done before the

radium itself was in working position. This enabled the necessary time and care to be given to the indispensable preliminary adjustments, as there was obviously no danger to anybody concerned in manipulating the uncharged apparatus. The amount of thought, care, and skill devoted to this and similar matters is beyond all praise.

It was decided from the first that these treatments should be confined to cancer of the mouth, tongue, larynx, and pharynx. In the first place these regions are easily accessible for inspection and treatment, and, in the second, surgery in order to prevail has to be of a very drastic character, and even then is often ultimately ineffective. Of recent years, since the development of radiotherapy, good results have been obtained by the interstitial use of small radium needles, but this means surgical intervention and considerable discomfort while the needles are in position. With beam radium therapy there is no surgery of access; the treatment is conducted externally, as with the x rays, and there is, of course, no discomfort arising from the presence of a number of inserted needles. It must, however, be understood that a certain amount of discomfort is inevitable during and soon after the treatment. Reaction of both skin and mucous membranes is bound to occur, but in general the patient's condition is much more comfortable than after interstitial radiation and incomparably more so than after the severe and permanently mutilating attempts of pure surgery to eradicate the growth completely. During the progress of each individual treatment every application of the unit is made by the radiotherapist, and the apparatus is kept empty of radium until all arrangements are complete. No one except the patient is present in the treatment room during the whole course of exposure; but communication between nurse and patient is rendered easy by an ingenious installation of microphones and loud speakers, while observation is conducted by the use of a system of periscopic mirrors. As the preface contributed by the Medical Research Council states:

"Of even greater importance than the actual therapeutic results so far recorded are the new technical methods which have been elaborated as the result of close co-operation between physicists and clinicians, and which are described in careful detail by the investigators concerned. The procedures used in this research, both for the treatment of patients and for the protection of the staff, should be applicable not only to radium beam therapy in its further evolution; they should be widely adaptable also to the needs and future developments of other types of radiotherapy for cancer. . . . The Medical Research Council have been impressed, moreover, not only by the high standard of work done under this scheme but also by the fact that the methods used are already serving as models to be followed elsewhere. They have accord-

¹ Medical Research Council. Report on Radium Beam Therapy Research, 1934-8. H.M. Stationery Office. 4s.

ingly accepted a proposal that they should assume chief responsibility for extending the research, and in this they are glad to be assured of continued co-operation by other bodies."

The general conclusions as to the value of this form of treatment are as follows. In cases in which the growth is early and localized its complete disappearance may be expected. When there is involvement of the lymphatic glands in close proximity to the original growth their enlargement can be made to disappear. Even with advanced stages of the primary growth and of local lymphatic involvement, in a small proportion of patients disappearance of the growth may occur; while in a large proportion many distressing symptoms are relieved. The report points out that, although it is too early to make definite pronouncements, it would appear that treatment of carcinoma of the mouth and throat by radium beam is at least as satisfactory as that by surgery or by interstitial radium therapy. And the results are obtained without mutilation of the patient. It has now been demonstrated that radium beam therapy, in competent hands, is a very valuable form of treatment. Further work is to be undertaken forthwith in which a 10-gramme unit will be applied to the treatment of cancer of the breast.

THE BLOOD TESTS BILL

Medical men who have studied the literature of blood grouping, and the use of blood tests in the courts of other countries for settling paternity disputes, are probably satisfied by now that the tests afford sound and valuable evidence. The rules for the inheritance of blood characters are proved beyond the shadow of a doubt, and pathologists who are familiar with the procedure regard it as one of the most reliable of all laboratory tests. The chief obstacle to the use of the tests in this country has been that the courts cannot order them to be made. As the tests cannot prove paternity but only, in certain cases, non-paternity, the mother has nothing to gain by acquiescing in them. Legislation is therefore necessary, and, after careful consultation with societies and individuals interested in the possibilities of the tests, Lord Merthyr has introduced a Bill into the House of Lords for the purpose of giving magistrates power to require a mother who asks for an affiliation order to undergo a blood test. The text of an official memorandum on the Bill is printed in our *Supplement* at page 362. It will probably come up for second reading soon after Parliament meets in the New Year.

The word "groups" is not mentioned in the Bill. The court may order blood tests, and these, as

defined, include any tests made with the object of ascertaining the inheritable characteristics of blood. If the research workers in haematology some day develop a test which will disclose individuality of blood, as to-day it is possible to show individuality of a finger-print, the Bill will not shut it out. The court may order a test when it thinks fit, but the Bill obliges the court to order the man and the woman with her child to undergo a test if either of the parties requests it to do so. Normally the request will come from the man, but it would not be fitting to give one party a right by statute and withhold it from the other. The object of the test is to show whether the defendant can be excluded from being the father of the child—a cumbersome phrase, but one familiar to pathologists. If the woman will not consent to the test, the court may not order physical compulsion, but must dismiss her application. Its ordinary power to adjourn at will is saved, and so the court may give the parties time to consider their position.

The question of who shall perform the tests is of the greatest importance. Unless the work is kept in the hands of experts who are familiar with it, mistakes are bound to be made and this otherwise valuable source of evidence will be discredited. The Bill provides, therefore, that the tests shall be carried out by an "approved person" in accordance with rules. The approved persons are to be chosen, and the rules made, by the Lord Chancellor, who is the officer of State at present responsible for the appointment of magistrates and the procedures in their courts. In forming his panel of approved persons he is limited to registered medical practitioners who are competent to carry out blood tests, and he is required to consult the President of the Royal College of Physicians. The rules are to govern the whole conduct of the tests, including the taking, identifying, and posting of samples of blood, the form of certificate to be sent to the court, the qualifications of the pathologists and the scale of fees and expenses payable to them, and any other matters which ought to be laid down. The Bill has been drafted to give the Lord Chancellor as free a hand as possible, in the confidence that, if it became law, his Department would make the best possible arrangements for implementing its provisions. After blood specimens have been taken according to the court's order and to the rules, the pathologist shall—it is proposed—send a certificate of the result to the clerk of the court as soon as may be practicable, in the form laid down by the rules. It will be the duty of the clerk to supply copies to both parties, and at the adjourned hearing he is to produce the original certificate. In order to save prohibitive trouble and expense, the Bill here provides for an important exception to the ordinary

laws of evidence: that the certificate shall itself be evidence of the result without the pathologist having to appear in court and swear to its correctness. There is precedent for this provision in the Food and Drugs (Adulteration) Act, 1928, which lays down that in a prosecution for adulteration the certificate of the public analyst may be received in evidence without calling the analyst himself. The principle is that the analyst is presumed to be competent and impartial, and a pathologist who has been specially chosen by the Lord Chancellor's Department as competent to perform blood tests obviously has an equal, if not a better, stamp of reliability. Nevertheless, the Bill provides that the court, the mother, or the man may call the pathologist to give evidence, but a party who calls him may have to pay the costs. The court may order the payment of all or part of the costs out of what are called the "local funds"—funds already in existence for defraying the cost of the defence of poor prisoners.

A blood test can never prove that a man is the father of the child; all it can do is to exclude an innocent man in about one-third of the cases. When it does not exclude the man it has no evidential value at all, for it does not show any greater likelihood that he is the father; it merely shows that, in common with several million other men, he may be the father. A court which does not realize this fact may, however, be misled into thinking that, because the test shows that the man may be the father, it therefore in some way corroborates the mother's statement that he is the father. In some countries an inconclusive result is not allowed to come before the court at all. Those responsible for the Bill have felt, however, that an English court should be trusted with all the available evidence. The magistrates will therefore have the certificate before them whether it is conclusive or inconclusive, but the Bill provides that if the certificate is inconclusive neither party may comment on it. A notable omission is any provision directing the court to accept the result of the test. Once the certificate is before the court it has precisely the same value as any other evidence, and its value is for the court to decide. The Bill, therefore, provides that a man who desires a blood test may have it, but may have to pay the cost. It gives the court power to use, at its discretion and at the public expense, a source of evidence which has already been proved in many parts of the world to assist greatly in the proper decision of paternity disputes. At present the English courts (the Bill will not apply to Scotland) hear nearly 7,000 bastardy applications a year, but relatively few of these raise a doubt so great that a blood test is needed to settle it. During the first year there might be a fairly

large number of applications for the test, but as the public became used to them, and as defendants realized that if they made a frivolous demand for the test they would have to pay, the numbers would soon settle down to a few hundred a year at most. They would perhaps be even less, because the existence of a reliable, if limited, means of disproving a false allegation of paternity would probably reduce the total number of applications for affiliation orders.

SEROLOGICAL DIAGNOSIS OF TYPHOID

Agglutination tests for intestinal infections have increased immensely in the refinement and complexity of their technique, and have gained correspondingly in significance. It is not long since the diagnostic importance of the O as distinct from the H agglutinin in typhoid fever was first generally recognized. A later development was the discovery by Felix of the Vi antigen and agglutinin, arising from the observation that recently isolated cultures varied in their agglutinability by an O serum: the degree of this agglutinability varied in inverse proportion to their virulence for mice. That this phenomenon is due to the existence of a distinct antigen associated with virulence is now generally accepted, and the consequences are important in two directions. Although the clinical evidence is not conclusive, there is good reason to believe that a therapeutic serum containing Vi as well as O antibody can influence the course of the disease, and such a serum is now available. The other direction in which these observations can be turned to account is that of diagnosis. Felix himself has recently asserted that the presence of Vi agglutinin is a certain sign of the carrier state. The significance of this agglutinin is made a good deal plainer in the paper by Major S. S. Bhatnagar, to be found at page 1195. He has made a study of its development in the course of the disease, and of its subsequent diminution, and it is clear that whereas other typhoid agglutinins persist for years after an attack the Vi agglutinin disappears from the blood almost as soon as the disease is over unless a carrier condition results: in that case Vi agglutinin remains in the blood just as long as living bacilli remain in the body. Another point brought out in this study is that in the previously T.A.B.-vaccinated individual who contracts typhoid Vi agglutinin is produced earlier and in greater amount than in the person who has not been inoculated: such individuals have a short and mild attack. It appears, therefore, that the presence of Vi agglutinin is the one and only certain serological sign of the presence of living typhoid bacilli in the body, whether during the disease or in the carrier: nothing can counterfeit it, neither a previous attack, vaccination, the anamnestic reaction, nor any other cause of positive reactions without active infection, such as may be obtained with other types of agglutination test. Bhatnagar has a further very practical contribution to make to this study in the discovery of a pure Vi strain of the typhoid bacillus.

This organism, if its peculiar character persists, is capable of much mitigating the technical difficulties of this study for anyone possessing a culture or securing suspensions of it, for even suspensions killed chemically have been found satisfactory, though for a few weeks only after preparation. Hitherto, owing to the instability of the Vi antigen, all this work has required the use of living cultures as agglutinable suspensions, a corollary to which is the freedom of stock sera from chemical preservative. Only a few laboratories have adopted Vi agglutination as a routine diagnostic method: it is safe to predict that many more will find it necessary to do so.

The typhoid bacillus has always been regarded as one and indivisible, a single entity from every point of view, and indeed in that sense an oasis of simplicity in the desert of complexity which constitutes the remainder of the enteric group and other species in the genus *Bacterium*. It is therefore somewhat alarming to read of the subdivision of the typhoid bacillus into seven "types." These, however, have been identified by Craigie and Yen¹ on the basis of susceptibility to different phages, an ingenious method for the ultimate pursuit of bacterial identity, and one the complexity of which in this case incidentally suggests doubts of the value of stock phages in therapeutics. The main interest of this method is epidemiological: thus of recent epidemics in this country that in Malton was due to Craigie's type F, Croydon to D₁, and Bournemouth to E. Such facts being known, further cases can be assigned with a fair degree of confidence to their presumptive source when the type of bacillus is ascertained and found to be the same as that in a contemporary or recent epidemic. These types are stable and a given typhoid bacillus can therefore be recognized, wherever it may have been between one case and another. This method promises in its authors' hands (for few others are likely to attempt it) to yield interesting information.

THE PROBLEM OF THE PARTIALLY BLIND

An article with this title by Sir James Barrett in the *Medical Journal of Australia* shows the difficulties that arise so soon as some piece of beneficent legislation is established. The blind are blind and need help. Help is provided for them. Then the poor-sighted envy the new economic security of the blind and strive to get the same for themselves. The Royal Victorian Institute for the Blind pays inmates the difference between what they earn and the basic wage. The partially sighted claim the same assistance. The standard adopted is the British formula. Those who are unable to count fingers at a distance of one metre are totally blind; those with vision up to 3/60 are partially sighted; and those with vision between 3/60 and 6/60 are considered in association with other evidence, such as contracted fields of vision and nystagmus. The partially sighted assert in some cases that the sight they have is of no benefit in their work. Yet Sir James Barrett cites examples where this assertion is proved untrue. An albino with 6/60 in each eye and nystagmus could have

been certified as blind, yet the man was brought up on a farm and managed it successfully. Sir James gives a list of cases where demands have been made for assistance, yet examination has proved the possession of effective or nearly normal sight. Some were cases of one-eyed persons whose remaining eye had normal vision. The moral is that no case should be certified for assistance as a blind or partially blind person without an examination by an ophthalmic surgeon.

SURGERY AND THE LIVER

In spite of careful pre-operative preparation and expert choice of anaesthetics there remain a proportion of surgical deaths, especially in jaundiced subjects, which are apparently due to liver insufficiency. Such fatalities as acute necrosis of the liver due to chloroform poisoning are of course well recognized, though luckily rare. In other cases, however, hyperpyrexia, oliguria, and a clinical picture resembling uraemia, ending in death, may follow not only operations upon the biliary tract but at times even quite "minor" surgical procedures. Such fatalities are sometimes spoken of as "liver deaths" or "liver-kidney deaths," and at necropsy some degree of hepatic necrosis is a usual finding. Some at least of the difficulties in the study of this subject, and particularly in guarding against such disasters in practice, arise from the lack of a reliable and at the same time relatively simple practical test of liver function. Before any operation, and equally before any anaesthetic, it is usual to examine the heart and lungs and test the urine, but there are few ways of testing the condition of the liver, which, in the absence of any special warning in the history, is often entirely ignored. It is, however, becoming now more and more the practice to give all patients, however slight the operation planned, additional glucose for some days before the anaesthetic. It is satisfactory to have further evidence² from Drs. F. H. Boyce and E. M. McFetridge that this measure is in fact effective. These workers have used a test of hepatic function which was first described in 1932 by Quick. The details of this test must be studied in the original papers, but it is sufficient to state here that it is based upon the excretion of hippuric acid in the urine after sodium benzoate has been taken by mouth. In spite of a number of objections to this test, common largely to all other tests of liver function at present available; it has given useful results, is easily carried out, and has already found a number of supporters. Employing it on a large series of subjects, Boyce and McFetridge confirm the value of pre-operative glucose and stress the fact that extra glucose is of real value during a fairly long period after operation. Much impairment of liver function, as shown by Quick's test, persisted in some of the patients tested for many days up to some weeks: in a certain number of cases the efficiency of the liver was more than halved after operation on the bile ducts. Anaesthetics administered to starved animals caused a much greater diminution in function than when given to well-fed animals. One important conclusion to which these workers came

¹ *Canad. publ. Hlth. J.*, 1938, 29, 448, 454.

² *Arch. Surg.*, 1938, 37, 401.

was that the post-operative fall in liver function was greater after spinal anaesthesia than after either ether or ethylene, and they firmly believe that spinal anaesthesia is not the safe procedure it is supposed to be. Not all workers would agree with this conclusion, and in a recent paper Ravdin² and others consider that in the surgery of the bile ducts spinal anaesthesia is the method of choice. But at least these investigations have demonstrated the fall in liver efficiency after operations, and the importance of post- as well as pre-operative administration of glucose in even normal individuals undergoing even simple operations. With the Quick test Boyce and McFetridge have also shown a considerable diminution in liver efficiency in thyrotoxicosis and a still greater post-operative fall after thyroidectomy. It is to this severe fall in liver function that they attribute many of the deaths after this operation, especially in poorly prepared patients: again they emphasize the value and importance of massive glucose therapy before and after operation.

CHOLERA IN RUSSIA

An important contribution³ has recently been made to the epidemiology and epidemiography of cholera as exemplified by its behaviour in Russia. The method of study adopted is more by way of the geographical and time relations of the several recorded outbreaks and their subsequent spread over the country than by the usual considerations of personal factors and mode and means of transmission. These topographical features are expressed by the word "geo-medicine," while the temporal elements are depicted by lines drawn on the map to represent the date of appearance of the advancing front of the epidemic, to which the term "isodates" is applied. A short review of previous contributions to the geographical study of this disease constitutes a preface wherein reference is made to the familiar dictum that "the movement of disease is from east to west against the rotation of the earth," and this is amplified by the observation that "the penetration of cholera is from east to west with distinct fading out the further westward it spreads," while the Elbe is cited as being the final barrier in its advance from Asia through Russia and into Germany. The first recorded outbreak of cholera in Russia was in 1823, when it appeared in the region of the Caucasus and Orenburg, but it did not then spread northward; in fact it was not until 1830 that an "all Russia" epidemic appeared. Since then Russia has experienced fifty-five "cholera years," but of these only thirteen can be regarded as "peak years," half of which could be designated as periods of limited or minor outbreaks only. Here it may be remarked that both morbidity and mortality are taken as indices of the character of the outbreaks so far as the statistics serve, and that reference generally is to European Russia, as the Asiatic part does not afford adequate records. In a series of eight "chartographs" the author illustrates his thesis by showing the "date lines" of the principal epidemics during the period in review. Of these the

first (the epidemic of 1830) is the simplest to follow, for the lines spread fanwise in almost regular order across the country, closer together where progress was slow and widely apart where it was rapid. There is, significantly, a central invagination on the western side to indicate an area that remained free although almost surrounded by cases. In the following year there was an exacerbation of the epidemic, and here the lines are much contorted. Then came a period of minor outbreaks or of complete freedom until 1847 to 1849, when a major epidemic swept right across the country in regular waves. Subsequent major outbreaks in 1853, 1855, 1870, and 1871 do not show the same regularity of advance, the lines being in the form of whorls and wide sweeps. The author aptly compares these lines of advance to the ripples of a disturbed water surface, and the irregularities to intervention of obstacles or residual ripples from a previous disturbance. Thus a striking picture of the invasion is produced. The months of the year most favourable to spread were August and September, closely followed by July and October, while the first four months of the year showed a marked decline. In explanation of the irregular and at times anomalous behaviour of the waves, interference by residual waves of a previous invasion—that is, the protective effect of exposure to infection—is not considered as sufficient, and the theory is advanced that there are in different regions cholera vibrios of a different inner quality and also a winter-resting phase. Be that as it may, the author has succeeded in representing the epidemic invasion of an extensive area in a new and graphic way that sheds a broad light on the epidemiology of the disease. He does not claim thereby to explain the inner dynamics of infectious disease, but hopes that the further use of this method will bear fruitful results.

THE MEDICAL DIRECTORY, 1939

The ninety-fifth edition of the *Medical Directory*, published at 42s. by Messrs. J. and A. Churchill, contains more material than any of its predecessors, but further typographical revision has resulted in a saving of four pages, despite a net increase of well over a thousand entries. The numerical summary of the medical profession shows that the names now number 61,109, being 1,215 more than last year's figure. As usual, the largest part of the present increase (543) has taken place in the provinces, which now contain 26,093 medical practitioners. In London there has been an increase of 159, in Scotland 208, and in Ireland 104. Entries under "Abroad" have grown by 228, while the numbers in Wales and in the "Services" section remain almost stationary. The time is long past since the *Medical Directory* needed an introduction to any member of the profession it serves so admirably. All we are called upon to do, year by year, is to take a few soundings and assure ourselves that the new edition is up to the high standard which the publishers have maintained from generation to generation. We find no falling off in the 1939 edition. It appears to be as accurate and up to date as care and intelligence can make it.

² *Surgery*, 1938, 3, 805.

³ *Z. Hyg. Infektkr.*, 1938, 121, 1.

The second point of special interest deals with the question of the organization of a national cancer service, and almost coincidentally with the publication of the Commission's report a Bill dealing with the subject has been introduced into the House of Commons by the Minister of Health.

Cancer Treatment at Large Centres

The importance of treating cancer at large centres is strongly urged by the Commission, and it is a point which should be obvious enough to all who give the subject impartial consideration. One function of the largest of the centres should undoubtedly be to provide facilities for instruction in the early signs and symptoms of the disease. Treatment to be effective must be early, as has been repeatedly urged in this *Journal*; and systematic instruction in the recognition of neoplastic diseases in their earliest stages is of vital importance. Such knowledge as this can only be obtained at institutions where a sufficiently large number of patients is collected.

Among the causes which hindered the establishment of an efficient national service in the past has been the acquisition of inadequate quantities of radium by small hospitals not working in co-operation with any recognized centre; and the same may be said of the private ownership and therapeutic use of small amounts. In both cases the objection is the same. Radium treatment to be effective needs in the first place to be in the hands of experts who devote the whole of their time to radiotherapy; it is in no sense a "side line" or a mere casual adjunct to surgery. In the second place the supply of radium available for the treatment of any particular case must be such that the patient receives neither more nor less than the optimum dosage with regard both to amount and distribution. Beyond all this it must be remembered that in many cases treatment by high voltage x rays is an indispensable adjunct to treatment by radium. For these reasons the indiscriminate supplying of radon or the hiring of radium needles to non-experts seems a most undesirable procedure, and the Radium Commission, in collaboration with the Medical Research Council, is doing valuable service to all concerned by insisting upon centralization as an essential to success.

Str strenuous efforts are being made to explore the possibilities of forming centres at Cambridge and Oxford. In view of the extraordinarily high quality of the research work upon the biological effects of radiation which is being carried out at the Strangeways Laboratory, Cambridge, the establishment of a clinical centre seems a matter of the greatest importance. The physical and experimental facilities are unrivalled, and it is to be hoped that the formation of a therapeutic centre in the near future will give practical expression to the ever-increasing developments of experimental radiology. At Oxford negotiations with the Nuffield Committee for the Advancement of Medicine are in progress, and although the immediate establishment of a national centre does not seem possible, a move in that direction has been made by an application for the loan of radium for gynaecological purposes.

Arrangements for Radium Therapy

The conditions regarding possible arrangements for radium therapy throughout the country are being thoroughly investigated by the Commission, and the conclusions reached will doubtless be of fundamental importance in forwarding any Government measures that may be taken towards the setting up of a national service. So far as can be seen the suggestions at present set forth coincide very closely with the declared aims and objects of the Commission from its beginning until the present time.

During the past year representatives of the Commission have visited many of the centres and are able to report

that all of them show a steady development of radiotherapy. This is in all respects a testimony to the valuable work which has been and is being done. Not less important is it to realize that for the efficient carrying out of a national campaign against cancer the co-operation of the general practitioner is essential. How this is to be secured is a matter for careful consideration, but obviously adequate instruction in the recognition of the earliest signs and symptoms is the first step towards obtaining a reduction in our high cancer mortality.

ROYAL AUSTRALASIAN COLLEGE OF PHYSICIANS

At the inauguration of the Royal Australasian College of Physicians at Sydney on December 15 the Royal College of Physicians of London will be represented by Dr. H. Morley Fletcher, formerly Senior Censor. It will be recalled that in the delicate work of drafting its constitution the founders of the new Australasian College took full advantage of the assistance afforded by the London College, with its wealth of experience and four centuries of tradition. The London College is therefore pleased to receive an invitation to send a representative to the opening ceremony.

Address from the London College

His Excellency the Governor-General of Australia, supported by the Prime Minister, will open the proceedings, and Dr. H. Morley Fletcher will present the following Address:

"To the Royal Australasian College of Physicians.

"We, the President and Fellows of the Royal College of Physicians of London, desire to send to the Royal Australasian College of Physicians our fraternal greetings and our hearty congratulations upon its successful inauguration. We have watched with much sympathy the steps that have been taken to bring the new College into being, and have regarded it as a privilege to put the long experience of our own College at the disposal of its founders. We do not doubt that the establishment of the Royal College of Physicians in Australasia will not only promote learning and good fellowship amongst physicians in that part of the Empire but will also be in the highest interests of medical science and practice.

"Along with this Address we have great pleasure in presenting the new College with a replica of our ancient caduceus, one of the insignia of office of our President. In the words of the original designer, Dr. Caius, 'the silver rod indicates that the President should rule with gentleness and clemency unlike those of old time who ruled with a rod of iron. The serpents, the symbols of prudence, teach the necessity of ruling prudently, while the Arms of the College placed on the summit indicate that gentleness and prudence are the means by which the College is sustained.' We are confident that the Royal Australasian College of Physicians will always be guided by these principles, and we cordially wish for it a long, useful, and prosperous existence."

Dr. Morley Fletcher will address the assembly on "Medicine—Past and Present," and, in addition to presenting the caduceus, will offer as a gift to the Library of the new College handsomely bound copies of Harvey's *Praelectiones Anatomiae Universalis* and *The Roll of the Royal College of Physicians of London*.

The December issue of the *Practitioner* has a number of articles specially devoted to "cold weather ailments." These include articles on the treatment of pneumonia by Dr. G. E. Beaumont, on chronic bronchitis by Dr. F. H. Young, on the clinical aspects of influenza by Dr. J. S. Scadding, and on vaccines and the common cold by Dr. Dennis Embleton.

Reports of Societies

TERMINAL DISINFECTION AND EXCLUSION OF CONTACTS FROM SCHOOL

At a meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health, with the vice-president, Dr. E. H. R. HARRIES, in the chair, a discussion took place on terminal disinfection and the exclusion of contacts from schools.

Dr. DUNCAN FORBES said that the discovery of the diphtheria carrier, and of mild cases of scarlet fever which were often overlooked, and the demonstration of the carriage of infection by spray gave good ground for the belief that apparently healthy carriers were the chief cause of spread in scarlet fever and diphtheria and that fomites played a negligible part in the spread of infection. It was on these grounds that in Brighton the old orthodox disinfection, first of mattresses and bedding in 1910 and later by spraying in 1921, was abandoned and the "spring clean" substituted. The "spring clean" consisted in the boiling of sheets and pillow-slips, the washing of blankets, the dusting of bedrooms, and the scrubbing of floors. It was important that the inspector should see that this "spring clean" was actually carried out, as, although it did not sterilize, it must reduce the amount and vitality of any lingering infection.

Statistics published by the Ministry of Health (Public Health and Medical Subjects No. 55) proved that the difference in results between orthodox disinfection and the "spring clean" was inconsiderable, and the added cost of orthodox disinfection was not justifiable in any but exceptional conditions. In order to allay anxiety a full disinfection after scarlet fever was still carried out in certain circumstances—for instance, if the mother was in an advanced state of pregnancy, in hotels and boarding houses, and in the homes of dairymen. After the "spring clean" had been tried out in scarlet fever and diphtheria it next replaced disinfection after cerebrospinal fever and pulmonary tuberculosis; in the former because of the known rapid death of the meningococcus after it left the body; in the latter because the usual mode of infection from persons suffering from pulmonary tuberculosis was by direct spray infection.

Exclusions from School

Home contacts after measles had not been excluded from school in Brighton since 1922. The reasons for this were (1) that such exclusion after the first crop of cases did not prevent a general infection of the school; and (2) that home contacts when excluded played with and infected neighbours' children who were at an age when the case mortality was high and who could not have the offer of any prophylactic injection of adult serum which home contacts of school-infected cases had. Chicken-pox contacts were not excluded because it was a real asset to get the attack over in childhood. With regard to scarlet fever, since 1932, whether the patient was removed to hospital or isolated at home, school contacts had been excluded for one week only without any apparent ill-effects; in Brighton 55 per cent. of scarlet fever cases were now nursed at home. An appeal was made for the early revision of the 1927 Memorandum on *Closure and Exclusion from School*, which, while claiming to be only advisory, really governed the practice of most education authorities.

Ritual Disinfection

Dr. A. TOPPING said that terminal disinfection was a survival from very early times when, there being complete ignorance of how infection was spread, herbs and

other materials, foul or sweet-smelling according to taste, were burned to combat miasmata or pest-bearing emanations. It was understandable then, just as was the practice of displaying a bunch of hyssop on the magisterial bench as a means of protection against typhus, but it was difficult to understand its persistence in our enlightened age. It was known that the organisms responsible were extremely short-lived outside the human body and that infection did not normally lurk behind picture rails or in the depths of a mattress but was almost invariably due to the direct passage of the causative organism from the throat and nose of a sufferer or carrier to those of a susceptible contact. Yet in deference to a completely uninformed public opinion the hoary witch-doctrine type of ritual connoted by terminal disinfection was continued. No matter how convinced he might be of the folly of the approved hocus-pocus, no medical officer could be blamed for playing for safety if he knew that he would be criticized if a second case arose and he had not burned his votive sulphur candle or sprinkled chloride of lime round the gullies—yet for more than forty years writers on public health had praised with faint damns, or had actually decried, routine terminal disinfection.

In America terminal disinfection had been almost completely discontinued, and there had been no evidence whatsoever of any corresponding increase in incidence. In this country several medical officers of health had to all intents and purposes abandoned it with excellent results. Dr. Duncan Forbes led the way in Brighton and had no cause to regret his action. The medical officers of many provincial towns and of certain metropolitan boroughs had followed suit, and instead of any increase in incidence of infectious disease there had been, in many instances, an actual diminution. Thirty years ago Dr. F. H. Thomson, then medical superintendent of the North-Eastern Hospital, discontinued any disinfection of wards changing over from one disease to another; a thorough washing, full free ventilation for only six to eight hours, and change of bedding were all he insisted on. His results continued to be at least as good as they had been when the full ritual was carried out. Another senior medical superintendent followed this example, but he countenanced the waving of a sulphur candle so that, on questions being asked, he could say that disinfection had been done!

No one could deny that under certain circumstances micro-organisms—for example, the haemolytic streptococcus—might survive for considerable periods outside the human body and occasionally retain their pathogenicity. Recent experiments by Dr. White at Queen Charlotte's Hospital showed that they could be recovered from dust; the moral was obvious, and there was no better way of removing dust than by a liberal use of soap, water, "elbow grease," and free full ventilation. The streptococcus which survived this for twenty-four hours must indeed be a stout fellow, and the odds against his being laid low by a variable concentration of sulphur or formalin fumes would be very heavy; even if entrenched in saliva or mucous discharges the streptococcus could not resist direct applications of soap and water. As regards bedding and other fomites, his opinion was that, as in the case of rooms, the high standard of disinfection normally prescribed was not justified by our knowledge of the viability of the organisms and the modes of transmission.

It is not normally necessary to subject mattresses to steam disinfection. Unless the organisms soaked into the depths in the patient's discharges it was difficult to visualize how it penetrated nightgowns, draw sheets, sheets, mackintoshes, and ticking. It was just as difficult to see how it found its way out and retained enough vitality to cause disease. When it was remembered that myriads of these same organisms were living in rude health in the throats and noses of people met in normal life it seemed somewhat supererogatory to spend money, time, and trouble in ruining mattresses on the off-chance that some

emasculated little orphan had found its way into their recesses. Where, for any reason, steam disinfection was really indicated, it should be reasonable. There was no justification for applying the standard necessary to kill anthrax spores or for surgical sterility if the potential infection was attributable to non-resistant organisms such as the *B. typhosus* or the haemolytic streptococcus. Dr. Topping continued:

"To sum up—in the case of the common infectious diseases of respiratory origin where current disinfection has been sensibly carried out no final disinfection other than cleansing the room with soap and water and allowing free ventilation is necessary; bed-linen, blankets, etc., should be washed; mattresses stripped and exposed to fresh air. Most of us feel in our hearts that this is all that need be done and that the spread of infection, were this the recognized routine, would not be greater than it is where more elaborate methods are in force. Until we become vocal, until the powers that be come down definitely on our side of the fence, and until we get the concurrence of the general body of medical practitioners, public opinion, unaware as it is of the real modes of transmission of these diseases, will, I am afraid, resent any change."

School Children as Contacts

In Dr. Topping's opinion routine rule-of-thumb exclusion of contacts from school was as much of an anachronism as was routine closure of schools. It argued either ignorance of epidemiology or unwillingness to face up to its teaching. In epidemic periods practically every child was a contact of the disease, yet the elaborate pretence of isolation was confined only to those in contact with a known case. Exposed children were kept away from healthy, well-ventilated schools and allowed to be in close contact with the younger and more susceptible children at home and in the streets: to play, to go to cinemas, and generally to mix at will out of school hours with their fellows. This was one of the best demonstrations of the ostrich technique that even illogical public health regulations could provide. The results of observance of this fetish had never been statistically worked out. What proportion of excluded contacts actually did develop the disease?—probably not more than $\frac{1}{2}$ per cent. What did exclusion cost in terms of lost education, grants, etc.?

Contacts as such, other than those who chance to be carriers—and this carrier state was largely independent of the contact for which they were excluded from school—did not convey infection. It was not until the prodromal malaise or catarrh manifested itself that the child was infectious. Where was this condition more likely to be promptly recognized, and where was transference of infection more likely to take place? In school with constant wide-awake supervision by teachers and school nurses in clean airy conditions, or in a stuffy home with a busy mother and a crowd of youngsters below school age? Exclusion of children in industrial areas was an insult to their intelligence and mumbo-jumbo of the worst type.

"The position is different if you are dealing with an isolated case of any disease and where the conditions either of the home or of the locality are such that contacts can actually be segregated from other children. But where the disease is established in an industrial area, pretended segregation of one small batch of the thousands of contacts is a waste of time and money. Variations in susceptibility are much more important than variations in the intimacy of contact, and no one, medical or otherwise, can postulate which of two children, one known to be exposed and the other only presumed to be, is likely to prove the greater danger to his fellows. I realize that any move to stop indiscriminate exclusion will be met by public outcry; exactly the same thing occurred when routine school closure was abolished and when the modified system of exclusion in measles epidemics was adopted. All are

agreed that both these measures have not resulted in increased incidence but have brought cases under treatment at a much earlier stage than formerly. Surely it is time for us as a profession to give an unequivocal lead in such an important matter."

Paths of Infection

Dr. M. MITMAN said there was a paucity of evidence of a scientific kind on the value of terminal disinfection. Available statistics indicated that there was no significant difference in the occurrence of secondary cases when terminal disinfection of the old type was abolished. He believed that the vast majority of the "inhalation" diseases were contracted by the close proximity of the new host to the infected person, the transmission of droplets taking place from one nasopharynx to the other. The effective range of such droplets was relatively small (distance factor) and the life of the organism outside the body was relatively short (time factor). Droplets suspended in the air were dispersed by ventilation and the majority of the organisms in them died as the result of drying and sunlight, so that their concentration was rarely sufficient to initiate an attack except in the vicinity of an infected person. Organisms in droplets and discharges deposited on inanimate objects were in like manner destroyed by sunlight and drying. Those which remained viable formed part of the dust and might be inhaled, but the concentration was seldom sufficient to result in disease, particularly if the dust had lain for some days. The viability of the organisms deposited on inanimate objects was influenced by the organic matter—for example, mucus and grease—in which they were embedded. A detergent like ordinary soap and water was therefore a good disinfectant. The efficiency of soap and water was demonstrated in cubicle and chamber nursing. The hands of an attendant were much more likely conveyers of infection than inanimate objects and were more difficult to clean, but washing seemed to be adequate. In alimentary infections insanitary disposal of excreta and unhygienic handling of food resulting in the contamination of food and drink were the chief factors. Inanimate objects, except bed-linen, played little or no part.

If these views were correct, persons and not inanimate objects were mainly responsible for the spread of disease. Concurrent disinfection of the discharges from the upper orifices of patients with respiratory diseases, and of the excreta of patients with alimentary diseases, was therefore particularly important. Terminal disinfection need be simple only: removal of dust by a vacuum cleaner or damp sweeping; throwing open the windows to clear the air; simple laundering of bed-linen and underclothes; exposure of mattresses and top clothes to air and sunlight; disinfection of utensils by boiling, destruction of toys and books by burning; and scrubbing inanimate objects with soap and water. In special circumstances departures from these practices were necessary. The only function of disinfection was to stop the paths of infection. Terminal disinfection of inanimate objects could not do this, because such objects did not institute a common path of infection.

PLEURAL EFFUSIONS

At a meeting of the Liverpool Medical Institution on November 17, with the president, Dr. E. GILBERT BARK, in the chair, Dr. ROBERT COOPE read a paper on pleural effusions, including empyema.

Dr. Coope said that absolute dullness was the cardinal sign of effusion, but there must be enough fluid present to cause a relaxation of the lung far enough away from the chest wall to ensure that the lung vibrations did not come through; this involved the accumulation of at least some 400 c.cm. of fluid. The percussion should be quite

light, especially in marking out the upper level of the fluid; the upper limit of the dullness was highest in the axilla. In the presence of a pleural effusion there were two factors which made a sound transmitted from the larynx and large bronchi more difficult to hear or feel on the chest wall: the lung was retracted and not so elastic or stretched as normally, and the sound had, as it were, to jump the change from air to water. Other things being equal, a large number of the sound vibrations were lost and never reached the hand or ear of the observer—so far lost, indeed, that there was silence. In particular cases all might not be lost. If there was not much fluid, and if, therefore, the lung was not markedly relaxed, the sound might jump the gap between lung and fluid and be well conducted. This often occurred in children, and many an empyema in a child had been missed by letting the diagnosis wait upon absent breath sounds over an area of dullness.

The cardinal sign, he repeated, was the absolute flatness of the percussion note . . . "if this is present do not be turned aside from the likely diagnosis of underlying fluid because you may hear breath sounds, or even bronchial breathing, coming through." He thought such things as Grocco's triangle, Garland's triangle, and Traube's space unimportant and often misleading; it would be more honest now to consign them to the historical museum.

Clear Effusions

In actual practice it was not difficult to eliminate the less common causes of serous effusion; the overwhelming majority of clear effusions were tuberculous, and to accept that fact frankly was the beginning of right treatment. Even in pre-radiological days Scandinavian workers found that if these patients were treated as ordinary hospital cases of acute illness, and discharged thereafter into the rough-and-tumble of the world, 40 to 50 per cent. of them became frank cases of pulmonary tuberculosis a few years later. With the coming of radiology careful workers found the proportion to be even greater. These effusions were only symptomatic of pathological processes in the underlying lung; the fluid was essentially an incident in the wider disease. If by reason of its bulk it caused mechanical difficulties, relief must be given by drawing some of it off, but the important question was how to deal with the diseased lung.

A lung with scattered subpleural tubercles only was not one which called for an artificial pneumothorax. Apart from any question of replacing the fluid by air, was the fluid to be removed in any case? To do so might cause rapid re-expansion of the lung, a change from lymphatic stasis to a flooding of the tissues with body fluids, and a real danger of dissemination of the lesions. The fluid would usually be absorbed within four to six weeks if left alone, even though pyrexia might persist in some patients over this period. After the acute stage was over these patients ought not to go back to the stress and strain of everyday life. With adequate sanatorium treatment over 90 per cent. would return to work and remain well. This remarkable contrast with what happened if the illness was merely considered as an acute episode called for courage on the part of the doctor; it was necessary to be frank with these patients in telling them what they might expect.

Empyema

Purulent effusions were of two types—true pyothorax and abscess of the pleural cavity (large or small) shut off by adhesions. It took time for adhesions to form; in the earliest stages of either a pneumococcal or a streptococcal effusion the pus would be thin and adhesions would not yet have formed. The practical difference between pneumococcal and streptococcal empyema was that an effusion complicating a streptococcal infection of the lung formed early, and the pneumonia—usually a bronchopneumonia—did not as a rule resolve so quickly; the streptococcal effusion tended to remain thin and cloudy for much longer

than did the pneumococcal. The pneumococcal empyema was not usually diagnosed until the pneumonia had resolved, the pus was thick, the empyema was walled off, and the condition was ripe for operation. "Evacuate pus straightway by free incision" was altogether too hasty counsel in the streptococcal cases. On the other hand, the over-cautious physician tended to be too dilatory in the pneumococcal ones.

It was true that pus must be removed, and the sooner it was removed the better for the patient both immediately and for the future. It was important, however, not to kill the patient in the process, and, moreover, the pus must be evacuated in such a way as to encourage the lung to expand. Some form of closed drainage was the ideal, during the acute stage of the lesion in the underlying lung and to favour proper expansion later. But if the patient came to the surgeon with large masses of fibrin and sloughs in the pleural cavity, then open operation might well be necessary, followed later by closed drainage. In purulent effusions, too, the condition in the underlying lung must be looked to for guidance in right treatment. Pus in the pleura was not only due to acute infectious processes in the underlying lung; there might be primarily a lung abscess, or a neoplasm, or phthisis, or even a sub-diaphragmatic abscess.

In the discussion which followed Drs. RONALD ELLIS, G. S. ERWIN, and WALLACE JONES took part, with Mr. JOHN T. MORRISON, Mr. HUGH REID, and Mr. F. RONALD EDWARDS.

At the same meeting Dr. H. WALLACE JONES showed a cinematograph film illustrating in slow motion various abnormal gait.

BRITISH ORTHOPAEDIC ASSOCIATION

Annual Meeting

The annual meeting of the British Orthopaedic Association was held in Birmingham under the presidency of Mr. NAUGHTON DUNN. A large number of members attended and enjoyed the scientific sessions, and also a tour, conducted by the Dean of the Medical Faculty, Dr. STANLEY BARNES, of the impressive new hospital centre and medical school. The association dinner was held at the Midland Hotel. A clinical demonstration was given in the out-patient department of the Royal Cripples' Hospital by Messrs. Naughton Dunn, Percival Mills, J. B. Leather, Wilson Stewart, F. G. Allan, A. G. Hendry, T. S. Donovan, and H. Donovan.

Coxa Plana.—Mr. H. JACKSON BURROWS (London) in this contribution epitomized the essay for which he had been awarded earlier this year the Robert Jones medal and prize of the association. He dealt chiefly with the pathology of the condition, and its relationships to similar lesions of other bones and to proven aseptic necrosis of bone. He described the essential histology of coxa plana as (1) an atypical subchondral necrosis which involved lysis of trabeculae, and (2) ingrowth of phagocytic and reparative young mesodermal tissue. The radiological criterion was destruction of trabeculae. Coxa plana could not be regarded as due to complete arterial obstruction, for in lesions resulting from such arterial obstruction—for example, aseptic necrosis of the femoral head following subcapital fractures—the normal architecture and texture of the bony trabeculae were preserved for a long time. Mr. Burrows discussed the experimental work which he had carried out in trying to determine the pathogenesis of coxa plana. Arterial obstruction alone did not produce the typical changes, and he felt, though he had been unable to prove, that venous obstruction and/or haemorrhage into the bony nucleus of the femoral head might play an important role. Infection, though unlikely, could not be ruled out entirely as a causal factor.

Bone Lengthening.—Mr. F. G. ALLAN (Birmingham) described in detail the method he employs for leg lengthening.

He discussed the indications for this procedure and the precautions which must be observed. From an analysis of the large series of patients on whom he had performed lengthening operations he concluded that two-inch lengthening could be safely and easily obtained, that tibial lengthening was more certain and easier to control than femoral lengthening, and that many of the complications experienced by other surgeons were due to extensive and unnecessary stripping of the periosteum and damage to the soft tissue.

Operation for Calcanéo-cavus.—Mr. BRYAN MCFARLAND (Liverpool) said the essential steps of the operation were the removal of a substantial wedge of bone from the posterior third of the os calcis, and its insertion into a niche on the dorsal surface of the neck of the astragalus, close to the articular surface for the tibia. If the wedge was inserted accurately it formed a block to excessive dorsiflexion. The procedure and patients before and after the operation were clearly illustrated by a cinematograph film.

Osseous Dystrophy following Icterus Gravis Neonatorum.—Dr. FRANCIS BRAID (Birmingham) gave a full account of two patients who had a disease characterized by (1) jaundice of the familial icterus gravis type at birth with acholia; (2) pathological pigmentation of the skin; and (3) a generalized cystic condition of the bones, which developed some time after birth. The bony changes might possibly have represented an accompanying developmental defect, or they might be secondary to cirrhosis of the liver (present in both patients) which could very well have disorganized the storage and utilization of vitamins.

Tuberculous Infection of Bursa over Great Trochanter.—Mr. T. S. DONOVAN (Birmingham) described five patients who had suffered from tuberculous infection of the subgluteal bursa. He made a plea for early excision; treatment by immobilization of the hip in recumbency had proved ineffective.

Snapping Jaw.—Mr. A. CAMERON ARMSTRONG (Liverpool) discussed the pathology of this condition, and an operation for the removal of the torn meniscus was described and illustrated by a cinematograph film. Through a short oblique incision in front of the ear the zygomatic arch was exposed and a half-inch of it removed (to be replaced at the end of the operation) immediately in front of the eminentia articularis. This procedure gave a clear view of the anterior and antero-lateral aspects of the joint, and excision of the meniscus was easy. In the two patients on whom the operation was performed a temporary paresis of the frontalis muscle developed, but recovery was complete in a few weeks.

Radiographic Changes of Childhood as Seen in Adult Life.—Dr. J. F. BRAILSFORD (Birmingham) showed an interesting series of radiographs of various bone dystrophies in patients with whom he had been able to keep in touch from childhood to adult life. He discussed the relationship between epiphyseolysis of the upper end of the femur and renal rickets, and described in detail the radiological appearances in the "pre-slipping" stage. He regarded infantile coxa vara as a localized bone dystrophy. Bone changes of a similar nature were sometimes seen in cleido-cranial dysostosis and in Albers-Schönberg disease.

Non-traumatic Dislocation of Toes.—Mr. SAYLE CREER (Manchester) gave an account of thirty-six patients in whom non-traumatic dislocation of one or more toes at the metatarso-phalangeal joint had occurred, the majority in connexion with hallux valgus and metatarsal arch defects; pes cavus was present in only one patient. In three cases there were plantar sinuses leading down to the dislocated joints. Mr. Creer disagreed with Branch's theory that the dislocation was produced by interosseous muscle action, and he demonstrated very clearly in a cinematograph film that these muscles on faradic stimulation had an action quite different from that ascribed to them by Branch. It was therefore concluded that the extensor tendons were the dislocating factors, in association, of course, with deformities already present. Treatment consisted of tenotomies of the extensors in the early stages; when the dislocation was long established excision of the base of the phalanx was necessary.

Local News

ENGLAND AND WALES

London School of Medicine for Women

The annual dinner of the London (Royal Free Hospital) School of Medicine for Women was held at the Savoy Hotel on December 1, Mr. E. Ulysses Williams presiding. In proposing the toast of "The School and the Hospital," the chairman mentioned various matters of domestic interest, including the honours and appointments gained during the year by old students, for all of whom the school maintained an affectionate regard. He also congratulated Mr. L. E. C. Norbury, surgeon of the hospital, on his election as a member of the Council of the Royal College of Surgeons. One event of the year was the installation in the physiological department of a cinematograph with sound, which would be of great advantage to those working there. The toast of "The Guests" was proposed by Mr. J. D. McLaggan, and was coupled with the names of Miss Helen Simpson (Mrs. Denis Browne) and Sir Girling Ball. He appraised Miss Helen Simpson's novels, saying that she was primarily a teller of stories and not one of those modern writers who probed too deeply into the abysmal depths of the human mind. Of Sir Girling Ball he said that his most distinguishing characteristic was his enormous fund of common sense. Among other guests he mentioned Mr. Denis Browne, who had acquired a great reputation as a soldier and a surgeon, but whom he remembered also as a tennis player—"up to Wimbledon standard" on the old court at the back of Great Ormond Street; their old friend Sir James Berry; Dr. Hamilton Fairley, who had come in the place of Sir Leonard Rogers; the Editors of the *British Medical Journal* and the *Lancet*; and Sir Walter Schröder, who, as the doyen among coroners, carried with him a tradition of dignity and courtesy which it would be difficult to match. Miss Helen Simpson began her reply with the remark that she was that "scourge of the profession"—a doctor's wife. Soon after entering that state she had a succession of illnesses which enabled her to look on the profession from the outside as well as from within and led her to offer a few observations as a patient on the manner in which doctors might better conduct their art or craft, or, as it used to be called in the Middle Ages, their "mystery." She thought it a mistake for doctors to take patients too much into their confidence. With scarcely an exception, what patients wanted from doctors was not reason but magic, and, indeed, the profession showed some appreciation of this when they used an astrological sign at the beginning of their prescriptions. Another consideration was that each patient believed himself to be unique, and resented being told that the doctor knew all about his particular complaint. It was a difficult task a doctor had to do—to keep patients in their place and at the same time to bolster up their conceit of themselves, to range them in classes and also to see them as individuals, and to combine the spirit of a vocation with the pursuit of a profession. It seemed odd to her that a profession embodying all these qualifications should for so long have been closed to women. She quoted from Lord Horder's inaugural address delivered at the school a few weeks previously that medicine seemed a natural profession for women to follow, and that the perfect doctor combined the woman's sensitiveness with the man's strength. It was a curious attitude, surely, to suppose that it was womanly to dress a wound but unwomanly to stitch it up, womanly to nurse but not to doctor. Women had something to give to the profession, perhaps not least because they had not quite the same herd instinct as men, nor quite the same reverence for tradition. Such challenge to tradition was not unhealthy in a scientific calling. Sir Girling Ball, who

also responded, spoke of a recent visit he had paid to the London School of Medicine for Women, and said that although the building dated back for nearly seventy years he had been struck by its modernity, especially the first-rate dissecting room. It lacked only space to expand, and he had wondered whether it would be possible to acquire a piece of land for this purpose from the Foundling Hospital. He felt that the schools in London should get much closer together, and in his capacity as Dean of the Medical Faculty of the University he intended to do his utmost to bring this about. There should not be all these separate bodies doing the same kind of work. A committee of the deans of the various medical schools was now in existence, and more and more important educational subjects came before it. After the chairman's health had been proposed by Mrs. Scott-Brown and duly honoured, the company broke up for dancing.

Scientific Treatment of Delinquency

Many influential people attended a dinner at the Savoy Hotel, London, on November 29 in aid of the Institute for the Scientific Treatment of Delinquency, under the chairmanship of Viscount Hailsham. The occasion was well timed in view of the recent publication of the Prison Commissioners' report and the introduction into Parliament of the Government's Criminal Justice Bill. The main purpose of the dinner was to raise funds to carry on and extend the work of the Institute at its clinic at 8, Portman Street, W. Some £2,000 a year is needed for maintenance and extension of the out-patient clinic to provide further staff and for research into the causes of crime. The clinic is operated by a staff of medical consultants and psychotherapists, who give their services voluntarily. The cases with which it deals are sent by magistrates, probation officers, social workers, and others; the opinions of the Institute's experts on these cases are co-ordinated by a director and a report is sent to the appropriate person, usually a magistrate. The speakers at the dinner were the Lord Chancellor (Lord Maugham), Viscount Samuel, Lord Roche, Mr. St. John Hutchinson, K.C., and Dr. Denis Carroll, a director of the clinic. The Lord Chancellor, commending the appeal, referred to the great progress made in penal reform during the present century. He said that the Prevention of Crime Act, 1908, and the Children's and Young Persons Act had effected a revolution in the law, and the new Criminal Justice Bill would bring about further important reforms. Lord Samuel said that in this Bill the Institute would have its charter. The dinner was organized by Countess De La Warr and Mrs. Harry Sacher. The appeal fund now exceeds £3,720, and more than £1,000 was collected in the room.

Lay Analysts at London Mental Hospitals

At the meeting of the London County Council on November 29 the Mental Hospitals Committee reported that it had considered a request by the director of research of the Institute of Psycho-Analysis for a small number of lay analysts in training at the institute to be allowed to be present to observe the reactions of patients when they were being examined at St. Bernard's Hospital, Southall. It was stated that the medical staff of the hospital were willing to co-operate in the arrangement, which meant the attendance at the hospital from time to time of two or three persons, not medically qualified, who were in training with a view to the practice of psycho-analysis. It was unusual for these students, in the course of their training at the institute or in their ordinary practice after training, to get experience of the major psychoses, and it had been represented that acquaintance with these would provide a useful background for other experience. The Mental Hospitals Committee had decided to grant the permission asked for, in the first instance for one year, when the arrangement would be reviewed. It was not proposed that lay analysts should be employed by or on

behalf of the Council either in the mental hospital service or under any arrangements made for after-care.

The proposal met with some opposition in the Council. Mr. F. S. Henwood moved and Dame Florence Barrie Lambert seconded an amendment instructing the committee to defer the permission until the Mental Health Committee of the British Medical Association, which was understood to be investigating the question of non-medical psycho-analysts, had reported. [The Mental Health Committee was appointed by the Council of the Association to inquire into the present medical equipment and provision for dealing with mental health in this country, with particular reference to the problems of the treatment and prophylaxis of the psychoneurotic and allied disorders.] Mr. Henwood considered that the proposal to allow persons who had no medical training to be present during the examination of patients was open to question. The patients were those who had been sent to a mental hospital under magistrate's order, they were at the mercy of the Council, and the Council had special responsibilities towards them. He also suggested that the question might be referred to the Council's medical officers as a body. The proposed action was defended by Mr. J. R. Oldfield, who said that the Institute of Psycho-Analysis was a perfectly proper body in every respect. The trainees were merely to be present as observers. The people observed were so acutely deranged that they would be unconscious of the presence of the trainees. He added that the Council had the only concentration of acute cases available in London, and if its assent were not forthcoming it was as good as saying that the trainees should have no experience at all. The medical superintendent of the hospital and his staff were in favour of the new departure, and the patients would in no way be jeopardized.

The amendment was defeated, and the report sanctioning the permission for the lay analysts to be present was approved.

SCOTLAND

Hospital Co-operation

The Secretary of State for Scotland, Mr. John Colville, discussing the need for co-operation in hospital services at the recent meeting of the Victoria Infirmary, Glasgow, said the work of voluntary hospitals was a natural expression of the spirit of liberty which was dearly prized in this country. The nation showed a sure instinct in cherishing the voluntary hospitals, but it would be a bad mistake for them to hold aloof from the municipal hospitals. The voluntary hospitals had recently sent him a memorial urging the need for co-operation in Scotland, and this initiative was a tribute to the voluntary hospitals. Changing conditions in medical science and the increased scale on which hospital services had now to be conducted had created the need for co-operation in this field of public work. Diseases that had formerly crippled or led to untimely death were being attacked with patient and confident skill, and the people of Scotland were healthier than formerly, although disease still took too heavy a toll. Mr. William Gray, chairman of the hospital, announced that Viscount Weir had given £7,000 for the building of a fracture clinic as recommended by the Departmental Committee on the Rehabilitation of Persons Injured by Accidents. The Victoria Hospital in the fifty years of its life had grown from an institution of eighty-four beds to one of 555 beds, treating 11,000 in-patients and 114,000 out-patients annually. Lord Provost Doilan of Glasgow referred to the antagonism which had formerly existed between the voluntary and municipal hospitals; this, he said, no longer existed in Glasgow because of an increasing understanding that the municipal and voluntary hospitals were not competitors but were working in the same cause.

Edinburgh Hospital Problems

At the annual meeting of the League of Subscribers to the Royal Infirmary, Edinburgh, it was stated that whereas twenty years ago the ordinary expenditure for maintenance was £87,000, last year it was £186,000, and the number of patients twenty years ago was 11,181, while last year it was 21,936. The chairman of the Board announced that the new maternity hospital and nurses' home were nearly completed, and would, it was expected, be in occupation by March 1, 1939. Maintenance of the maternity block was going to add about £30,000 a year to expenses, and it would be necessary for the citizens of Edinburgh to take a greater interest in the maternity work. The managers of the Infirmary were ready to meet representatives of the local authorities to discuss matters involving the municipal hospitals and the Infirmary, and among other things a contributory scheme would require careful consideration. Mr. Andrew Eunson, honorary secretary of the League, reported that there had been a considerable increase in contributions. In 1918 they received £1,600 from employees in public works and businesses; in 1938 this had risen to £32,000. The Edinburgh municipal hospitals were not full, while the Infirmary had a waiting list of over 3,000. The solution seemed obvious—namely, to utilize the empty municipal beds for the waiting patients. It had been suggested that a contributory scheme should be started under which the treatment of members of the scheme would be paid for either in the municipal hospital or in the Infirmary. Such a scheme, however, could not be adopted for Edinburgh alone, because more than half of the patients in the Infirmary came from outside of the city. A contributory scheme must therefore apply to the whole of the south-east of Scotland, but the charter of the Infirmary did not permit the institution of a general system of payment, and the attitude to a contributory scheme of the other voluntary general hospitals in the area was not yet known.

Correspondence

Primary Abdominal Tuberculosis

SIR.—The contribution of Drs. Stefan Engel, Ruby O. Stern, and G. H. News on the danger of primary abdominal tuberculosis in children (November 19, p. 1038) is both timely and welcome, as it calls attention to a condition which is preventable and is a far more serious menace than commonly supposed. They have well shown how frequently a fatal termination may be anticipated in numbers of very young children. Nevertheless, I believe the infection exists in many children and may often be overcome by suitable treatment and in some cases cured naturally without its presence having been diagnosed or even suspected. It would be of value if a similar investigation to theirs were conducted in children from the age of 5 to puberty. I have been interested to observe the much higher proportion of cases of primary mesenteric tubercle admitted to this hospital in recent years. This is probably in part due to improved early diagnosis, though it must be admitted that many were only discovered at laparotomy, especially for appendicectomy.

Except in fulminating cases where meningitis supervenes, comparatively early diagnosis should not be so difficult as the authors would have us believe. Even apart from family history or conditions known as likely to produce infection the general appearance of the child, his faeces, malaise, irritability, apathy, capricious appetite,

occasional attacks of colicky pain relieved by warmth and pressure, sometimes diarrhoea alternating with constipation, in a few cases vomiting, should lead to a tuberculin test being applied. Stigmata of tuberculosis as described by Rivers, ichthyosis, deflected nasal septum, and even squint, though by no manner of means invariable, do sometimes occur and should put us on guard. Locally, frequent absence of abdominal reflexes and localized abdominal tenderness on deep palpation with slight muscle guarding are common, and in more advanced cases the doughy abdomen associated with matted intestines and sometimes free fluid in the flanks makes the presumption of tuberculosis very probable. In acute cases there may be tenderness in the flanks and occasionally very easily palpable enlargement of iliac and groin glands on the side affected. Pyrexia is an uncertain sign, but a moderate degree in untreated cases is common.

On the pathological side haematological examination should be undertaken, as it may afford valuable confirmation of clinical findings, and the sedimentation reaction of the blood should always be ascertained. Examination of the stools for occult blood and tubercle bacilli should invariably be made, and the by some discredited Triboulet test for intestinal ulceration or, as I would prefer to call it, intestinal permeability has, in my hands, proved valuable both as one of the many aids to diagnosis and also as a guide to the conduct of treatment. X-ray examination may be of little if any value at the onset, but later is often of very real help.

I cannot but believe that if investigations somewhat on these lines were undertaken in suspected or doubtful children many cases would be discovered and subsequent disability, invalidism, or even death averted. The tuberculin tests, harmless if of the Pirquet variety, may supply a useful initial hint. Failure to undertake these and perhaps other investigations may lead to dissemination and dangerous sequels. These facts are beginning to be appreciated and are already having favourable effects. They should be emphasized.—I am, etc.,

Alton, Hants, Nov. 28.

HENRY GAUVAIN.

Glycosuria

SIR.—The matter of which I give details confirms what I have long suspected—namely, that diabetes is an insidious disease, often of slow progress and of long duration before its discovery, giving no distress to its victim and no means of diagnosis to the physician save by urine testing, and causing essential cell destruction. Volunteers for the auxiliary fire service of the air raid precautions scheme in the borough of Crosby had a sample of their urine tested. Of 132 men examined, eight were found to have glycosuria, their ages ranging from 26 to 40 years. The precipitation on testing was rapid and copious in all but one case. Each of the eight men said that he felt quite well and strong, and all save one followed occupations involving hard work; every objective symptom was absent except that one man stated that at times he had pains running down the limbs, which he attributed to a "little rheumatism." On physical examination the vision of each man was normal; no examination of the disk was made. Diagnosis was only possible by examination of the urine.

Each man was referred to his own doctor. One practitioner, to whom I had referred one of the men, said that in the last few weeks, on testing samples of urine, he had discovered five cases of glycosuria which, owing to the absence of subjective symptoms and physical signs,

would otherwise have been missed. He went on to state that his late professor of medicine at Edinburgh had said in his lectures that anxiety and mental stress are among the causative agents of glycosuria, and had pointed out its greater incidence among the Jewish race. This, the professor considered, was due to so many of the Jews being engaged in banking, money-lending, speculation, and keen businesses, and, in addition, to their being treated with antipathy in so many countries that mental stress and anxiety were ever present. My friend's view was that the recent cases he had encountered were due to like causes, induced by business disturbances, fear of war, and general unrest caused by the international situation.—I am, etc.,

Liverpool, Nov. 28.

VINCENT J. GLOVER.

Haemorrhage following Tonsillectomy

SIR,—Mr. D. W. Ashcroft, in his article on haemorrhage following tonsillectomy, in your issue of November 26 (p. 1079), states: "According to the literature ligation of the external carotid artery is of doubtful efficacy in any type of tonsillar haemorrhage on account of the extensive anastomosis of this vessel through the circle of Willis." The external carotid artery does not enter, even indirectly, into the formation of the circle of Willis, nor do any of its branches. The major part of the blood supply of the tonsil is derived from the rami dorsales of the lingual artery, which anastomose with those of the opposite side, as also do the palatine arteries which contribute branches to the tonsil, and ligation of the external carotid may therefore be ineffective.

Mr. Ashcroft further states: "... it is desirable that effective measures for the control of any bleeding should be instituted before transfusion becomes necessary." I think that many surgeons will agree with the view that transfusion is of value more for its haemostatic effect than for its mere replacement of blood lost, and that it should no longer be regarded as a late resource.—I am, etc.,

Pituitary Extract in Third Stage of Labour

SIR,—It was interesting to read the article by Dr. G. W. Blomfield in the *Journal* of November 26 (p. 1083), on the giving of pituitary extract with a placenta still in the uterus. I have done this in cases of retained placenta on four occasions during the past six months.

The first time was for a patient who had some degree of post-partum haemorrhage and after many attempts had been made to express the placenta. When first seen she was badly collapsed, her pulse could not be felt, and she had a flabby uterus which continually relaxed and filled with blood clot, in spite of a controlling hand on the fundus. Her condition was too poor to permit of a manual removal, so 1 c.cm. of pitocin was injected intramuscularly and the blood clot gently expelled from the uterus and vagina, the abdomen and fundus being very tender. The uterus then contracted on to the placenta and the bleeding ceased. Intravenous glucose, 20 per cent., was administered. The bed was already raised at the foot; an electric blanket was put over the patient and $\frac{1}{4}$ grain morphine was given. A watch was kept on the fundus, but no excessive bleeding occurred. The patient's condition gradually improved, and fourteen hours later, after a good sleep, she was given an anaesthetic and the placenta was expressed. During the puerperium she had a raised pulse and temperature for some days, but was able to get up on the tenth day and went home normally on the fourteenth day.

The second and third cases were similar, but not so ill when first seen.

The fourth case was one which I delivered myself under light chloroform and ether anaesthesia. One and a half hours after the delivery a third attempt to express the placenta failed. This patient had had a long labour—terminated by forceps for foetal distress. Her condition was good, but she was obviously tired; there was no bleeding and the placenta seemed firmly attached to the uterus. Remembering how well the other ill patients had responded, this patient was given pitocin also and the nursing staff were asked to keep a watchful eye on her and call me if necessary. Next morning—that is, about six hours later—the placenta was easily expressed. This patient's puerperium caused no anxiety.

In my experience repeated attempts to express a placenta generally cause marked shock and collapse, while a manual removal, even at its best, is likely to cause sepsis later. It is probably unsafe to risk haemorrhage by leaving a placenta without first giving an oxytocic drug. Therefore pitocin to prevent bleeding, followed after a good rest by expression of the placenta, seems the most natural and rational treatment for this otherwise difficult condition. I consider, however, that it is essential to have a good, trustworthy nurse when leaving these patients; these four patients happened to be in hospitals or nursing homes, but I remained with the first case for some hours before I felt it would be safe to leave her.—I am, etc.,

Bristol, Nov. 30.

MABEL F. POTTER.

The Occipito-posterior Case

SIR,—The second letter from Dr. David Price (*Journal*, November 5, p. 968) is indeed obscure, and does nothing to rectify the unfortunate impression caused by his first letter. He fails to explain how he finds the position of the occiput, the sutures of which are obscured by oedema, if he omits the "whole hand" examination. He speaks of the "impacted unadvancing head," below which a cervix cannot fully dilate in a reasonable time. Surely this is the picture of delay due to disproportion. Finally, he would have us believe that it is wise to deliver the child in the absence of uterine contractions through a cervix not fully dilated. Why such haste to complete the delivery? I cannot agree that Dr. Price's ideas will ever be considered good obstetric practice.—I am, etc.,

Aplastic Anaemia with Complete Recovery

SIR,—The case reported by Dr. T. H. Boon (*Journal*, November 19, p. 1041) prompts me to record a somewhat similar case recently under my care.

On July 6, 1938, a man aged 36 had several infected stumps of teeth extracted and bleeding was severe. He was admitted to the Royal Naval Hospital, Haslar, on July 8. He looked very ill on admission, his breath was foul, and there was continuous oozing from the infected gums. He stated that his health had been excellent; in fact, he had been playing water polo up to a couple of weeks before admission to hospital. His previous history was of interest. In 1921 he contracted syphilis, for which he had intensive arsenical treatment for two years. In 1930 he again developed a primary sore, and again had arsenic and bismuth therapy; he was considered cured in 1933. In 1937 he again developed a primary chancre, and again had courses of arsenic and bismuth, the last course having been completed in June, 1938. On admission to hospital on July 8 his blood count was: red

cells 2,250,000; haemoglobin 43 per cent.; white cells 5,200 (polymorphs 35.5 per cent.; lymphocytes 58 per cent.; monocytes 6.5 per cent.); reticulocytes 1.6 per cent.; coagulation time $3\frac{1}{2}$ minutes; bleeding time 3 minutes. The spleen and liver were not enlarged, and his blood pressure was 110/50 mm. Hg. On July 12 the blood picture had become worse: red cells 1,500,000; haemoglobin 30 per cent.; white cells 1,800 (no immature cells seen). There were retinal haemorrhages in both eyes; his temperature was swinging between 100° and 103° F.; his mouth was grossly septic and bleeding was continuing from the gums; his nose was bleeding. On July 20 a purpuric rash was present on the trunk. On July 22 the blood picture was: red cells 2,250,000; haemoglobin 45 per cent.; white cells 2,000 (polymorphs 26 per cent.; lymphocytes 65 per cent.; monocytes 4 per cent.; myelocytes 5 per cent.). During the fortnight since admission treatment had consisted of three transfusions—each of 500 c.cm. of blood with citrate solution—and injections of liver, pentide, and soluseptasine, with iron and marmite by mouth. Though the blood picture had shown only a slight improvement his general condition was markedly improved. The oozing from the gums ceased, the mouth was cleaner, and he was taking nourishment well.

On August 12 his blood picture was: red cells 2,250,000; haemoglobin 43 per cent.; white cells 1,600. Another transfusion of 300 c.cm. of blood with citrate solution was given. The administration of pentide and soluseptasine had been stopped, but iron, liver, and marmite were being given. On August 26 there was a setback in the blood count: red cells 1,750,000; haemoglobin 41 per cent.; white cells, 1,800. The diagnosis was aplastic anaemia.

On September 12 a sternal puncture was done and the bone marrow obtained was examined and found to be normal. This caused the diagnosis to be changed to that of achrestic anaemia, and it made the prognosis more hopeful. This optimism was justified, because from then onwards the blood picture steadily improved without any remission. On October 8 the blood count was: red cells 3,500,000; haemoglobin 79 per cent.; white cells 4,400. On November 4 the blood count was: red cells 4,250,000; haemoglobin 91 per cent.; white cells 6,200. It may be mentioned that a fractional test meal showed the presence of free hydrochloric acid, and that the blood Wassermann and Kahn tests were negative.—I am, etc.,

J. G. HOLMES,

Surgeon Commander, R.N.

Haslar, Nov. 21.

Grenz-ray Therapy

SIR,—The annotation in your issue of November 26 (p. 1093) on the subject of Grenz-ray therapy is interesting and stimulating.

It is now two years since I invited Dr. Z. A. Leitner to work in my physiotherapeutic department at St. Mary's Hospital in order to introduce this much-neglected branch of physiotherapy. Results have been extremely good in the local treatment of lupus and other forms of tuberculous skin disease, and in obstinate and chronic cases of poikiloderma vascularis and other rarer and more difficult skin cases where many forms of treatment had been tried in vain. Grenz rays have also shown their great value in the general treatment of certain constitutional diseases. Cases of total alopecia come under this heading, as do certain types of allergic diseases, such as bronchial asthma, migraine, etc. All these cases need great experience and judgment, and scrupulous care regarding dosage. In these we have seen, surprising and even dramatic results.

Unfortunately the possibilities of such modern methods as Grenz rays are as yet little understood in general hospitals to-day. What is needed in all our physio-

therapeutic departments is a much larger number of cases that have not yet arrived at the chronically hopeless stage. Only then can adequate research be done and controlled investigations that are urgently needed carried out.—I am, etc.,

JUSTINA WILSON.

Perforated Gastric Ulcer

SIR,—The article by Mr. Alan H. Hunt and Dr. Eric C. O. Jewesbury on perforated peptic ulcer in organic nervous disease (November 26, p. 1082) brought to my mind a recent remark of a surgical colleague that "the worst place to perforate is in hospital, for the houseman so seldom thinks of perforation in a patient already in one of his beds." To the first part of his sentence, and for the same reason, I would add "or just before admission to a medical ward."

On three occasions I have discovered a patient with a perforated gastric ulcer in one of my medical beds; each time the diagnosis was clinched in my mind by the finding of absent liver dullness, and each time I have been told in rebuttal that there was pneumonia at the base of the right lung—a correct finding so far as it went, for the lesion there was secondary to a collection of purulent fluid under the diaphragm. It is true that none of them presented the so-called typical board-like rigidity of the abdomen; but the absence of liver dullness is a sign surely almost, if not quite, pathognomonic, sometimes occurring reasonably early, sometimes late.

Many good-sized ulcers of the lesser curve are curiously painless in certain phases, and the physician may sometimes be surprised at not being able to elicit a typical ulcer history from the patient. Moreover, an appreciable number of perforations do not necessarily give a "typical" picture, even in the absence of organic disease of the nervous system. There seems to be no need, therefore, to bring in the presumption of a special interference with the normal pathway of pain impulses just because these patients happened to be suffering from organic disease of the nervous system.—I am, etc.,

Liverpool, Nov. 28.

ROBERT COOPE.

Anti-pernicious Anaemia Principle in Urine

SIR,—The presence of the anti-pernicious anaemia principle in urine has been investigated by several groups of workers without conclusive results having been obtained. This may be due partly to the difficulty of separating without loss of potency the small quantities of the anti-anaemia principle that may be present in a state suitable for parenteral injection (and free from toxic substances), and partly to the fact that many of the examinations for anti-anaemia potency have been done with the rat or guinea-pig tests, which, while often used by Continental workers, have now been rejected as unreliable by most others.

In their paper Dr. Edouard Jéquier and Major G. R. M. Apsey (*Journal*, November 5, p. 934) obtained positive reticulocyte-provoking responses with urine (as judged by an increase in reticulocytes from 0.5 to 2.3 per cent. initially to maxima of 3.1 to 4.5 per cent. after injection into rats), while Mr. B. D. Thornley (November 26, p. 1113) did not get any response when his extract of normal urine was tested clinically in one case.

During the last six years my chemical collaborators in this department have prepared in various ways extracts of urines for examination for the presence of the anti-

anaemia principle. In this manner we have made and examined six series of urinary extracts which have been tested for anti-pernicious-anaemia potency in the usual manner in controlled cases of pernicious anaemia. Our results have been as follows:

Series 1 and 2 were prepared from the urines of patients with subacute combined degeneration of the spinal cord, treated with daily parenteral liver preparations. Each patient supplied about 20 to 25 litres of urine, and the extracts when given to untreated cases of pernicious anaemia produced no remissions in Series 1, but normal remissions in Series 2. The two series were prepared differently.

Series 3 and 4 were obtained from normal urines—40 litres of urine from each normal individual being used. The extracts in Series 4 gave normal remissions in test patients, but those in Series 3 gave painful reactions and were discontinued.

Series 5 was prepared from urines from untreated patients with pernicious anaemia—35 to 40 litres of urine being collected from each. These extracts were inactive when tested clinically.

Series 6 was made from 23 litres of urine from one treated patient with pernicious anaemia in remission. This has only been given so far to one test case with a doubtful response.

Our impressions are that whatever amount of anti-anaemia principle may be excreted in the urine it is not present in very large quantity.—I am, etc.,

Manchester, Dec. 1. JOHN F. WILKINSON.

Vitamin B₁ and Insulin

SIR,—We have read with interest Dr. A. Gordon Watson's description of a diabetic case treated with vitamin B₁ (*Journal*, November 26, p. 1111), which suggests that the vitamin had a beneficial effect on the diabetes and reduced the insulin requirements. Our experience is not so fortunate. We have treated a fairly large series—well over a hundred—of insulin cases with big doses of vitamin B₁, a few by injections, most orally. While the neuritis has often been benefited, we have never observed any effect for better or for worse on the carbohydrate tolerance or insulin requirements. Many of our cases have been under close observation, and we certainly should have noticed any improvement in them.—We are, etc.,

R. D. LAWRENCE.

M & B 693 in Gonorrhoea

SIR,—I have read with much interest and profit the preliminary report by Dr. R. C. L. Batchelor and his colleagues published in the *Journal* of December 3 (p. 1142), and agree with their conclusion that M & B 693 is the most potent anti-gonorrhoeal agent at present. These authors investigated 102 cases in both sexes and achieved 91 per cent. of apparent cures. The standard of cure aimed at by the authors was not achieved in all 102 cases. Had this standard been achieved it is reasonable to expect that their rate of apparent cure would have been lower. From the scientific point of view one is more interested in the permanent rate of cure, however large or small the number of cases; of course the greater the number the better. There is almost a specific drug for the early infections of syphilis in the form of arsenobenzol or bismuth preparations. The standard period of observation is a minimum of two years. In view of this I suggest that the minimum period of observation after treatment of gonorrhoea with chemotherapy should be two months in male cases and six months in female cases—if we are to find out the permanent rate—in gonorrhoea by

chemotherapy. It is interesting also to point out that Dr. Batchelor has not used vaccines in his valuable investigations, and does not advocate delayed chemotherapy.—I am, etc.,

R. MARINKOVITCH,

Salford, Dec. 3. Venereal Diseases Officer, City of Salford.

Air Raid Precautions

SIR,—Most people will agree with Dr. F. G. Chandler's criticisms of the hospital organization during the September crisis. I think, however, that it is fair, and I believe correct, to remind Dr. Chandler that the Ministry of Health had the "baby" of responsibility handed to it less than three months before the actual crisis, and, further, that the individual hospitals were only informed in detail what was expected of them within two weeks of the crisis.

I am not in a position to say what individual or Government Department was responsible for this amazing want of foresight, nor does that matter at the present time, as I hope, and feel convinced, that the organization that is now being got out by the Ministry of Health will be very different from the hasty organization in September last.

I know nothing about the future organization, but it seems to me that the most important step is the provision of potential base hospitals round the large cities, with advanced base hospitals rather closer for those abdominal and head wounds which can without much risk be moved out of the danger area. I agree with Dr. Chandler that the work of the casualty clearing stations in the next war will be much more in the nature of first-aid-post work than was the case in the last war. It seems fairly certain, also, that a great number of young men will have to deal with this type of work while the senior surgeons and physicians are in the base hospitals, where teaching will have to be carried out when hostilities allow of it. Whether the casualty clearing stations will have to be so numerous as to require other buildings than the existing hospitals of the cities seems to be doubtful, but that portions of the hospitals should have special protection in order to deal with those cases that cannot be transported out of the danger zone would seem to me to be essential. Had the war started in September I am convinced that within a few weeks the hospitals in the centre of London would have been closed down until such protection could be given to make them into first-aid posts.—I am, etc.,

London, W.1, Dec. 2. MALCOLM DONALDSON.

SIR,—Recent letters in your columns, statements in Parliament and elsewhere, and admissions by responsible spokesmen of the department mainly concerned have all emphasized the inefficiency of what has been attempted in the way of air raid precautions. But the authorities whose labours over some years have accomplished so little are still in charge, and signs of any radical improvement are not evident. Major W. V. Fawcner-Corbett, in the *Journal* of November 26 (p. 1114), puts the case for an organization on lines copied from the Army. As an official who has had to do with local attempts to work the A.R.P. scheme I should like to support that. In my opinion the endeavour to organize efficient A.R.P. with unpaid volunteers is illogical and doomed to failure. Apart from the folly of concentration on obtaining volunteers before schemes were prepared or arrangements in hand for training (in my districts equipment for instruction is not yet to hand), how can the allegiance of such untrained volunteers be kept in face of the counter-attraction of the Women's Auxiliary Territorial Service, or

batteries which I understand works and factories are to organize from their hands? I would suggest that the protection of the civil population from air raids is a military responsibility, the neglect of which may lose a war, and that a force for this purpose should be organized on the lines of the Territorial Army. One must realize that it is not a question of temporary arrangements for protection in a situation which is not going to recur, but that from now on it is a permanent national need.—I am, etc.,

Guisborough, Yorks, Nov. 29.

C. R. GIBSON.

SIR,—May I support the point brought forward by Dr. F. G. Chandler in the *Journal* of December 3 (p. 1175). During the crisis emergency schemes were organized in the central hospitals which, as examples of rapid improvisation and within the limits imposed by the controlling authorities, were excellent. The essence of the schemes was that medical and nursing personnel should be concentrated in the available hospitals in the areas in which most casualties were likely to occur. The urgency of the situation probably made these limits necessary then, but, like Dr. Chandler and many others, I am very disquieted at the possibility of their still applying in a more carefully worked out scheme. The amount of destruction of medical and nursing personnel which would occur from the continued chance bombing of such strongly concentrated collections would in no long time raise replacement problems of national, and possibly international, importance. But already one hears suggestions that the more permanent schemes may be on similar lines, and there is talk of adding to the medical and nursing concentration at the central hospitals a further concentration of voluntary workers for bandaging, canteen work, and other such auxiliary services, the atmosphere being more suggestive of the Boer War base hospitals than modern front-line institutions. Study of the methods of modern warfare, which is to-day being forced on even the inexpert, points to two principles to which all medical emergency schemes should, in my opinion, conform:

1. The principle of holding the front line by a minimum of screen troops. Applied to the medical services this means that the central hospitals in emergency should be staffed by the minimum number of medical men and auxiliaries, with facilities for reinforcements if required. The great bulk of the medical and nursing personnel should be carefully conserved.

2. The principle of dispersal. This means that such medical services as have to be retained in the central area should be scattered in multiple small units rather than concentrated in large institutions. In this connexion the use of suitable accommodation in large commercial houses is at once obvious, the units being based for purposes of personnel and supply on the corresponding hospital of the district.

—I am, etc.,

London, W.1, Dec. 5.

DAVID H. PATEY.

Control of Small-pox in India

SIR,—I think that Dr. C. Killick Millard's critics (*Journal*, December 3, p. 1180) have missed the point. It is plain from his letter (November 19, p. 1061) that Dr. Millard is not in any doubt concerning the infectivity of variola minor, while on a number of occasions he has placed on record his appreciation of the fact that recent successful vaccination protects the individual. What he does affirm now (if I read him aright) is that vaccination as carried out in India to-day has lamentably failed to control small-pox among the native community; and the remedy which he suggests as being apparently in his own

view more practicable than measures aiming at more and better vaccination is the deliberate introduction of variola minor as a prophylactic measure against variola major.

For myself, I have grave doubts, for technical and moral reasons, regarding the practicability of his suggestion; but I would base my main criticism on the grounds that the whole rationale of Dr. Millard's suggested procedure arises from the false premise that variola major and variola minor cannot coexist in a community.—I am, etc.,

Dartford, Dec. 4.

J. PICKFORD MARSDEN.

SIR,—Dr. J. D. Rolleston (December 3, p. 1180) has unfortunately misread my letter (November 19, p. 1061). So far from stating that variola minor was not infectious, I used the fact that it was infectious as being a great advantage in a country like India, as compared with vaccination. It is, of course, true, as Dr. Rolleston points out, that variola minor is not entirely free from risk; but compared with variola major it is certainly a trivial disease. And, after all, vaccination itself is by no means entirely free from risk.

As regards Dr. A. G. Newell's letter (December 3, p. 1180), although he opposes my suggestion that inoculation with variola minor might with advantage be substituted for vaccination, his arguments seem to me strongly to support it. He agrees that the mortality from small-pox in India is appalling, and he stresses the enormous difficulty of controlling the disease by vaccination, owing to the social habits, the superstitions, and the prejudices of the people. But when he says that there is no evidence that vaccination has lamentably failed in India I would reply that that all depends upon how you look at it. By his own showing the methods hitherto attempted for the control of small-pox in India, the chief of which is vaccination, have lamentably failed, and in any case the mortality figures for small-pox are proof of this. It is not a case of blaming either officials or vaccination; but we have got to face the facts. Dr. Newell's remedy is education of the people as to the value of vaccination. But surely the medical authorities in India have been striving to do this for years; and even in our own country, with all our educational and other advantages, similar attempts have not been too successful. Finally, he objects to my suggestion because it might undermine faith in vaccination so far as this has already been established. I do not think that this would necessarily be the case at all, but admitting for the sake of argument that it might have such an effect, is this a sufficient reason for refusing to try a fresh method if it offers a reasonable prospect of success, seeing that the existing method has so greatly failed?

Lieutenant-Colonel H. C. Keates (December 3, p. 1180) fails to appreciate the fundamental difference between the effect of vaccination in protecting the individual and its effect in protecting the community. It is only as regards the latter that I accuse vaccination of having been a lamentable failure, and I repeat that the appalling mortality from small-pox in India, after vaccination has been "pushed" as far as ever was practicable under the existing conditions, is sufficient evidence of this. As to the effect of vaccination in protecting the individual, I am probably just as orthodox as Lieutenant-Colonel Keates himself.

In conclusion, may I point out that India and the Far East was the "home" of small-pox inoculation long before the discovery of vaccination. The idea of inoculation, therefore, would not be alien to the philosophy of the people of India. It is possible that they might accept it quite as readily as vaccination. But in the old days of

inoculation the distinction between variola major and minor was not known. It was variola major which was inoculated, and it is not surprising that the results were often disastrous. To-day the greatest care would be taken only to inoculate with the virus of variola minor, so that the results should be infinitely better. I submit, in all seriousness, that the suggestion to substitute inoculation with the virus of variola minor in place of vaccinating with calf lymph is worth consideration by the medical authorities in India. Saturate the population with variola minor and substitute a trivial disease for one which, in spite of the efforts hitherto made, is still a veritable scourge. There would still, of course, be a field for vaccination for the white population, for small-pox hospital staffs, for officials, or for any others who appreciated that the protection conferred by vaccination, although complete for a time, is not permanent, and therefore the vaccination requires to be repeated.—I am, etc.,

Leicester, Dec. 4.

C. KILICK MILLARD.

Decline of Breast-feeding

SIR.—In all the correspondence on this subject there has been no convincing evidence that food supply *per se* plays an important part in enabling a mother to supply breast milk to her infant. In the discussion that took place on the modern decline of breast-feeding at the first session of the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Dr. Alan Moneriff said that "he thought there was a danger of making too much fuss about nutrition. A poor diet during lactation might cause anaemia, but the milk did not fail in quantity until the woman was about to drop; and even then the quality remained." Dr. Ruth Young also gave her experience in India, where the Hindus were forbidden to eat meat, fish, or eggs; they were too poor to buy milk and had little fruit, yet "the infants usually gained steadily on the breast for the first seven or eight months."

In this country public health authorities can in necessary cases supply free milk and free dinners to nursing mothers, and the amount of help given in this way is increasing every year, so that it is difficult to agree with those who stress the importance of diet, vitamins, and general nutrition in maintaining a supply of breast milk. After all, the breast is not a filter for food but a gland requiring stimulation to carry out its function. We all know that the colostrum period, especially in primiparae, is often prolonged to seven or even ten days, so that a little extra nourishment is required until full lactation is established, but when this has been accomplished the extra food can be discontinued. I feel certain that more attention to the technique of breast-feeding by the general practitioners and nurses who attend to these cases is urgently required.—I am, etc.,

London, W.8, Nov. 29.

RONALD CARTER.

New Menstruation Toilet

SIR.—We ought to be grateful to Dr. E. Lawton Moss (November 26, p. 1113) for his timely warning against the use of vaginal tampons, and especially for mentioning the danger of consequent sterility. A recent experience illustrates this point, and although a single case proves nothing it may serve to make one think.

A healthy young woman came to me last June with a profuse leucorrhoea due to a cervical erosion. She had been married for ten years and was childless; she has used tampons intermittently since girlhood and regularly for the last two years. The erosion disappeared entirely after four weekly

swabbings with picric acid in spirit; within three months, however, the discharge had returned, and again there was a large erosion. This unusually rapid recurrence made me question her more closely, and, with a somewhat defiant air, she told me the tampon story. She was with difficulty persuaded to stop using them—and she is now enjoying a normal pregnancy.

This case must be typical of many, where endocervicitis is an unsuspected cause of temporary sterility, and where the original suggestion of using these plugs has come, as in this case, from a doctor.—I am, etc.,

Guildford, Nov. 29. C. R. McLAUGHLIN, F.R.C.S.Ed.

SIR.—Dr. E. Lawton Moss's letter in your columns on the use of absorbent vaginal plugs as protectives at the menstrual period prompts me to relate an experience I have had of this method of personal hygiene.

Some months ago I was consulted by an intelligent and responsible young lady about a vaginal discharge which had appeared four days previously, on the cessation of her period. She stated that menstruation had always been regular and normal, and she had never before suffered from intermenstrual discharge. On inspection I found a thin, blackish-brown, offensive discharge escaping from the vagina, and digital examination revealed a soft mass tightly packed high up in the vagina. This proved to be one of the tampons now on sale for the menstrual toilet. On its removal a rush of foul discharge escaped, and the odour from the saturated plug was exceedingly offensive. The cervix showed patches of hyperaemia where the dressing had been in contact. The patient had used this form of protective for the first time during the last period. She was astonished to find she had left a plug *in situ*.

The case emphasizes, I think, Dr. Moss's contention that such dressings are liable to become infected. It also shows that a real danger exists of one being left behind until it becomes an offence and a danger to health.—I am, etc.,

Leamington Spa, Dec. 1.

DOROTHEA M. TUDOR.

SIR.—The "new" menstruation toilet is not so new. Apart from the fact that ballet dancers have used cotton-wool plugs at all times, I can vouch for the bacteriological integrity of more than one of my patients who has used some or other of the incriminated methods for over four years. A novice in this field, after reading Dr. Moss's letter, might conclude that women are in the habit of plugging the vagina when the necessity arises, and of leaving these plugs *in situ* until they become "offensive and infected," while at the same time deadly bacteria are given a chance to breed in the "dammed-up blood" above the plug. In fact nothing of the kind ever takes place, nor does it seem that even Dr. Moss has ever seen a case of "vaginitis, cervicitis, *B. coli* infection . . . or sterility" caused by this method. He only asserts that these conditions are "likely to result" from the new menstruation toilet.

On the contrary, they are not at all likely to occur, because all women who use any of these methods know that they must change their sponges or cotton-wool plugs every three hours, or before the full capacity of their soaking power is reached. They know that they must change them in time because menstrual blood does not, as a rule, coagulate, and will therefore not be "dammed up" above the plug. The incubator situation Dr. Moss describes in such gloomy terms in fact does not arise, and while I have seen some of my patients discontinue the use of this method because they disliked the presence of a foreign body in the vagina, I have never seen a case, nor heard

of one, in which this method has been the cause of any inflammatory or bacteriological trouble. And if any further proof of the harmlessness of this method be needed it might be found in the fact that it is recommended particularly by women doctors who have found it beneficial and harmless in their own experience.—I am, etc.,

London, W.1, Dec. 1.

EDWARD ELKAN.

SIR,—Mr. E. Lawton Moss (*Journal*, November 26, p. 1113) designates the insertion of tampons by the woman during the catamenia as a "new menstrual toilet." Actually it has been in use in America for the past few years (see *J. Amer. med. Ass.*, March 12, 1938).

Apart from the bacteriological considerations mentioned by Mr. Lawton Moss, with the possible resultant ascending sepsis, sterility, etc., these tampons act as a mechanical foreign body in the vagina. To insert into the vagina during periods of recurrent increased epithelial proliferation a pack composed of cotton, wadding, or gauze, which swells up and loses its pristine smoothness, is to increase the susceptibility of the vaginal mucosa to the results of mechanical irritation.

I have found in the few cases I have advised that in the majority of the women some blood escapes past the tampon, requiring the added protection of a small vulvar pad within the labia. There are also obvious difficulties in connexion with various classes and types—for example, virgins, multiparae with some degree of prolapse and/or gaping vulva, etc. The method, in its present form, cannot be advocated as a routine.—I am, etc.,

London, S.W.1, Dec. 4.

MICHAEL COHEN.

Social Pathology

SIR,—I thank Dr. Hilda Weber (November 26, p. 1115) for that word! . . . "The absence of action against environmental factors which frustrate the basic needs of a community will lead to the decline of individual and therefore of national health" admirably expresses a fundamental truth. It is far-reaching in its meaning. Her palliative for London, though helpful, might be disappointing because it does not go very deep. People who are herded into masses shrink into themselves in self-defence and need altogether more space for leading their own lives. Repression ultimately leads to explosion, while real life remains. I am only writing this, however, to ask that this correspondence should be continued. We are all afraid of these subjects because they easily encroach on politics, but a detached medical or scientific outlook is badly wanted.—I am, etc.,

Leitchworth, Nov. 26.

NORMAN MACFADYEN.

The Services

Surgeon Commander R. C. May, M.C., has been appointed Assistant to the Medical Director-General of the Royal Navy at the Admiralty.

DEATHS IN THE SERVICES

Lieutenant-Colonel STANLEY EVERARD LEWIS, R.A.M.C. (ret.), died at Shears Green, Gravesend, on November 23, aged 61. He was born on October 8, 1877, and was educated at Glasgow University, where he graduated B.M., Ch.B. in 1902. He entered the R.A.M.C. as lieutenant on August 31, 1903, became lieutenant-colonel on June 1, 1926, and retired on August 31, 1932. After retirement he was employed at Gravesend. He served through the war of 1914-18, and was mentioned in dispatches in the *London Gazette* of October 19, 1914, and January 1, 1916. He was awarded the Legion of Honour (fifth class).

Medico-Legal

A CONFLICT OF DUTIES

CRIMINAL ABORTION AND MEDICAL SECRECY

The question whether a doctor who learns in the course of a professional relationship that a crime has been committed should inform the authorities in breach of his obligation of secrecy is no new one. It arises most often in the case where a woman, dying of septicaemia as the result of a criminal abortion, tells the doctor the name of the abortionist. Most medical men are familiar by now with the classical dictum of Mr. Justice Avory in 1914. Charging the grand jury on a bill against an abortionist, he said:

"I cannot doubt that it is the duty of the medical man to communicate with the police, or with the authorities, in order that steps may be taken for the purpose of assisting in the administration of justice. No one would wish to see disturbed the confidential relation which exists, and which must exist, between the medical man and his patient in order that the medical man may properly discharge his duty towards his patient; but there are cases, of which it appears to me that this was one, where the desire to preserve that confidence must be subordinated to the duty which is cast upon every good citizen to assist in the investigation of a serious crime. . . . It may be the moral duty of the medical man, even in cases where the patient is not dying, or not unlikely to recover, to communicate with the authorities when he sees good reason to believe that a criminal offence has been committed."

In reply to this opinion the Royal College of Physicians of London passed a series of resolutions laying down that a medical practitioner is not justified in disclosing confidential information without the patient's consent; that if he is convinced that a criminal abortion has been practised he should urge the patient to make a statement if to do so would not prejudice her recovery; that if she refuses he is not legally obliged to take any further action; and that if she should die he should refuse to give a certificate and should communicate with the police.

If a patient with religious belief is sincerely convinced that she is about to die, and makes in that belief a statement to any person, that statement may be received in evidence at a trial for her homicide. It need not even be reduced into writing at the time. Needless to say, a practitioner who hears a dying declaration ought to take it down in writing, and if possible have the patient sign it or make her mark. It should if possible be in her actual words, and if questions are put, the questions and answers should both be given. If there is time, the doctor should summon a magistrate, who can take her evidence on oath. If reasonable notice can be given to the accused person to enable him or his legal adviser to be present and cross-examine, her deposition will be admissible if she dies, even though the rules covering the admissibility of a dying declaration have not been satisfied.

A Recent Case

This controversy was revived recently in the Paddington coroner's court.¹ Mr. Ingleby Oddie was inquiring into the death of an unmarried woman who had died of septicaemia after an operation. Dr. Arnold Harbourn, who is a divisional police surgeon but was attending the woman privately, said she told him that she had had an illegal operation, and he sent her to hospital. She was dangerously ill and was probably going to die, though an operation might have saved her life. He consulted his solicitors and his defence society on whether he should report to the police what she had said, and his solicitors and the society advised him that it was not his duty to do so. The coroner said that he did not blame Dr. Harbourn for his action. He pointed out, however, that if the doctor had taken steps to warn the authorities that the

¹ *Times*, November 8, 1938.

woman had had a felony committed on her and was dangerously ill, a dying statement might have been taken from her in the presence of a magistrate. He recalled Mr. Justice Avory's charge to the grand jury and added that, although the doctor had a moral obligation to preserve the confidence of his patient, in certain circumstances that confidence should be overridden. The position, he said, was by no means satisfactory and ought to be considered by the authorities. He feared that, until something was done, the secrecy which always surrounded these cases would be maintained and many criminal abortionists would go scot-free, as he had no doubt they often did now.

The Doctor's Duty

The views of the British Medical Association have often been expressed, and are quite clearly stated in the *Medical Practitioner's Handbook* (p. 110). They are that the suggestion that a doctor should volunteer information in such circumstances should be strenuously resisted, in the belief that nothing should be done to prevent anyone who is ill from consulting a doctor in the fullest confidence that his secret, even if it be that he has been concerned in the commission of a crime, will not be reported to the authorities.

The question was discussed by the Medico-Legal Society in June, 1927.² There Lord Riddell stated that the views of the British Medical Association and the Royal College of Physicians did not meet with universal medical approval, and expressed the opinion that, considering the prevalence of abortion, the leaders of the profession were undertaking a serious responsibility in advising practitioners in such emphatic terms to disregard illegal acts of a most pernicious character. While everyone recognized the necessity and importance of respect for medical confidences, doctors must also recognize that the rules regarding these existed for the welfare of the community and "not for the aggrandisement or convenience of a particular class." These words probably represent a fairly large body of legal opinion. Sir William Willcox considered that if the doctor fails to persuade the patient to make a clean breast of what has happened, then perhaps it is his duty to inform the authorities after taking legal advice.

There is no prospect of any solution to the dispute, and it is hardly to be imagined that an *ad hoc* Bill will be introduced into Parliament.

A STRANGE CAUSE OF DEATH

A householder and his wife were much annoyed by her brother, a youth of 21, who persisted in coming to the house and causing trouble, in spite of warnings. On one occasion the husband fetched a rook rifle and prodded the youth with it to frighten him. The youth tripped over a flower-border and fell against the man. The rifle went off and the bullet lodged in his neck. He was taken to hospital and put on the operating table. The surgeon had located the bullet and was about to remove it when his revolving stool slipped and he fell on the floor. He changed his gown and gloves and returned after about six minutes. The bullet had now altered its position, and he was trying to find it again when the patient's breathing suddenly became shallow and stopped. At the trial of the husband at Denbigh Assizes last month³ the surgeon said he would not care to express an opinion on the cause of death. Dr. G. Roche Lynch said that if the surgeon had not fallen the bullet would have been taken out much earlier and the patient would have been on the way to recovery; in his opinion the death was due to chloroform poisoning.

Mr. Justice Hilbery, in addressing the jury, said that no degree of provocation excused the killing of a man. A person could use such force as was necessary to bring about ejection

and no more, but a lethal weapon was an excessive thing to employ against an unarmed man. Death by chloroform poisoning was a risk attendant upon any operation. The jury would have to ask themselves whether death ensued through an operation advised by medical men, and if their answer was in the affirmative they could not convict of manslaughter. In order to convict of unlawful wounding they must be completely satisfied that the injury had been done unlawfully. They acquitted the accused on both charges.

A DEATH FROM PENTOTHAL

At a recent inquest held by Mr. A. D. Cowburn, the Camberwell coroner, an anaesthetist gave evidence that he had administered pentothal intravenously to the deceased woman at a second operation undertaken a week after labour. It was very quick-acting and gave the minimum amount of shock. A pathologist said that he had found nothing wrong with the operation, and that a proper dosage of the drug had been given. In his opinion death had been caused by the effects of the drug, toxæmia, and the effects of the operation. The coroner, recording a verdict of death by misadventure, said that there had been no neglect, no mishap, and no accident. He did not altogether approve of the drug, but that was a matter for discussion, and for weighing all its advantages and disadvantages.

Universities and Colleges

UNIVERSITY OF OXFORD

At a Congregation held on November 29 a gift of £200 a year for two years from Mrs. Hugh Watts in augmentation of the stipend of the assistant director of the Institute of Experimental Psychology was accepted.

UNIVERSITY OF CAMBRIDGE

The Vice-Chancellor has appointed Sir Edward Mellanby, K.C.B., F.R.S., M.D., of Emmanuel College, Secretary of the Medical Research Council, to be Rede Lecturer for the year 1939. The place and subject of the lecture will be announced later.

UNIVERSITY OF LONDON

Dr. H. Letheby Tidy has been elected Dean of St. Thomas's Hospital Medical School in place of the late Professor Leonard S. Dudgeon.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates for the degrees of M.B., B.Ch. have satisfied the examiners in the examination indicated:

PATHOLOGY AND BACTERIOLOGY.—Mary E. Budding, T. C. H. Davies, T. Griffiths, D. I. Harries, A. B. J. Hill, O. Howell, R. T. Jenkins, G. A. Jones, J. E. Lloyd, Mary E. Lloyd, S. Love, T. Walker.

OBSTETRICS AND GYNAECOLOGY.—C. Davies, W. H. Harris, J. C. Herapath, H. R. Hudd, Margaret Morgan, C. Thomas, W. Williams.

The following candidates have satisfied the examiners:

PHARMACOLOGY.—Doreen M. E. Cranch, Enid Curran, Joan B. Davies, D. F. V. Johnston, Gwenllian M. Lewis, *W. C. D. Lovett, I. Mazin, J. B. Randall, Nest G. Richards, J. H. Stranger, E. R. Treasure, *Glenys J. Wade, G. A. Wright.

* With distinction.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At the annual meeting of the College, held on December 1, Dr. Alexander Goodall was re-elected President, and the following were elected to form the Council for the ensuing year: Dr. Edwin Bramwell, Dr. John D. Comrie, Dr. Charles McNeil, Dr. A. Fergus Hewat, Dr. D. M. Lyon, and Dr. A. Graham Ritchie. Dr. Comrie was nominated Vice-President.

At an extraordinary meeting held immediately afterwards the honorary fellowship of the College was conferred on Sir Charles Bickerton Blackburn, O.B.E., M.D., Sydney, first President of the Royal Australasian College of Physicians.

Obituary

WILLIAM McDOUGALL, M.B., F.R.S.

Professor of Psychology, Duke University, North Carolina

In the death of William McDougall there passes from our sight a very notable—in some ways a unique—figure.

He was born in 1871, and after studying at Owens College, Manchester, proceeded to St. John's College, Cambridge, where he graduated in medicine. He studied also at St. Thomas's Hospital and Göttingen University. As a young graduate he took part in the anthropological expedition to New Guinea and Borneo in company with

Rivers and Myers. In 1902 he was appointed Reader in Psychology at University College, London, and from there he proceeded to Oxford as Wilde Reader in Mental Philosophy. During the war he served in the R.A.M.C., and when Littlemore was opened as a hospital for functional cases he became senior clinical officer and gathered round him a group of younger men, some, like Hadfield, his old students. He returned to his academic duties for about a year, when he left and was appointed

professor of psychology at Harvard University—the chair once occupied by William James. In 1927 he left Harvard to occupy the chair that he held at his death at Duke University. His academic career was thus somewhat anomalous. It reflects more credit on the man than on the academic groups involved. At Oxford he gave his full time and unstinted energy to his academic work though the salary was negligible, the status that of a Reader, and the position (as it continues to be) subject to an archaic maldescription. After the Armistice he returned to his Readership. He said to a friend, "I have done my best to serve my country during the war. I have returned, to have my laboratory taken from me." It is impossible to believe that Oxford seriously wished to retain his services.

In 1927 he left Harvard to go to a new and incomplete university. The change no doubt cost him a good deal. But his difficulties at Harvard were of a somewhat different nature from those at Oxford. There he had expressed his crusading impulses in uncompromising attacks on materialists, behaviourists, and others who suffered from that "uncriticized ability" which is characteristic of lesser breeds. And so he found himself at the age of 56 founding a new department of psychology in a new university and far removed from the academic traditions in which he had begun his career. There, in the last eleven years of his life, he succeeded in establishing a faculty that has already given proof of considerable vitality.

McDougall's most prolific literary phase was during his Harvard years. Before that he had written *An Introduction to Social Psychology* (1908), *Body and Mind*, *Pagan Tribes of Borneo*, and *The Group Mind*. The first of these is probably the work that has commanded the widest attention. It is safe to predict that this volume

will continue to be studied when much of the more fashionable psychology of to-day has been forgotten. At Harvard he wrote *National Welfare and National Decay*. That volume contained truths that society on both sides of the Atlantic still needs to assimilate. There followed *An Outline of Psychology*, *Ethics and Some Modern Problems*, *The Indestructible Union*, *An Outline of Abnormal Psychology*, and *Character and the Conduct of Life*. In the *Outline of Abnormal Psychology* McDougall attempted the thankless task of presenting and evaluating the various schools of modern psychology. In *Ethics and Some Modern Problems* he returned to his favourite problem of race deterioration and dealt with it more faithfully than acceptably. (The volume consisted of lectures given to American audiences.) The last phase—that at Duke University—saw the publication of *Janus*, *the Conquest of War*, *Modern Materialism and Emergent Evolution*, *World Chaos*, *The Energies of Men*, *Religion and the Sciences of Life*, *The Frontiers of Psychology*, and—finally, last month—*The Riddle of Life*. None of these was a major work. In some ways perhaps the most notable is *Religion and the Sciences of Life*, in which McDougall expresses a religious conviction to which he had been driven by his persistent study of purpose in human behaviour. Possibly the change of attitude represented in that volume emanated also in some measure from a more intimate source: the book was written after his son Alan had been killed in an R.A.F. display; and McDougall was a remarkable family-man. Those who had the privilege of knowing him in the family circle cannot dissociate his psychology and sociology from his enviable background of domestic happiness.

If McDougall was a crusader he was by no means narrow (as is the manner of most crusaders) in his objects of interest and of condemnation. His enthusiasm for eugenics and his denunciation of race deterioration were but the counterpart of his Lamarckian zeal. That zeal expressed itself in the amazingly persevering rat experiments. These well-known experiments were intended to show that an acquired aptitude could be transmitted. Pavlov, too, made similar experiments. After accepting his results as positive he subsequently repudiated them. But McDougall was indignant that the great Russian scientist contented himself with a mere matter of four generations, whereas McDougall was already at the twenty-fifth. These experiments, it is believed, are still in progress, and it is to be hoped that they will be carried on till a conclusion one way or another is beyond evil. In these, as in all his experiments, McDougall was pre-eminently practical and honest.

Over his well-known theory of the instincts he fought many battles, notably with his former ally, A. F. Shand. But it was the behaviourists who drew his most ruthless denunciation in this field, and it was certainly a source of satisfaction to him in his later years to observe the pendulum beginning to swing back from the extreme position it had reached in American psychological thought. Freud and his school were obviously marked out for McDougall's criticism. While he was ready to accept much of what is central in the tenets of that school, he was impatient of a great deal that he regarded as unwarranted assumption. In particular he came to grips with Freud over "the group mind." Of Jung he was, as one might expect, much more tolerant, seeing that they both stood for purposive psychology. It was characteristic of McDougall that when he was over 50 he submitted himself to analysis by Jung. He could not have done so if he had been what some of his critics are prone to assert—arrogant and inflexible. In a lecture at University

College he told the dream which had caused Jung to terminate the analysis, and in the telling he revealed a simplicity and sincerity which few men of his standing could have emulated.

In recent years McDougall gave a good deal of attention to psychic research. He took part in some inconclusive experiments with mediums; his completely impartial summing-up of evidence, pro and con, was very impressive. This same interest caused him to initiate the well-known telepathic experiments at Duke University which are still being carried on by Dr. Rhine.

McDougall was said by some to be dogmatic, but his dogmatism belonged to his manner rather than to his thought. He was a deductive rather than an inductive thinker; fearless when he felt conviction; uncompromising when he detected the illogical or the unscientific; utterly disinterested when he felt impelled to attack the popular or fashionable view; a keen observer of his fellow-men in their most primitive as in their most sophisticated environments; a very loyal friend and a very true gentleman.

H. C.-M.

[The photograph reproduced is by Elliott and Fry, Ltd.]

HAROLD PRITCHARD, M.D., F.R.C.P.

Emeritus Physician, West London Hospital

Dr. Harold Pritchard, whose death we announced with regret last week, was born in 1876 at Chester, where his family lived, and began the study of medicine at Liverpool and went on to St. Bartholomew's Hospital. He took the Conjoint diplomas in 1901 and graduated M.B., B.S.Lond. with honours in medicine in 1904, proceeding to the M.D. in 1906 and taking the M.R.C.P. soon afterwards. He was elected F.R.C.P. in 1926. His first appointment was that of house-physician at Addenbrooke's Hospital, Cambridge, which he held for several years. On returning

to London he was appointed junior demonstrator of pathology and casualty physician at Bart's, and edited the *St. Bartholomew's Hospital Journal* for a year or two; about this time he was appointed assistant physician to the West London Hospital and to the Miller General Hospital at Greenwich. In the first weeks of the war Pritchard gave up all civilian work to join the staff of the Duchess of Westminster's Hospital at Le Touquet (No. 1 Red Cross), and received a com-

mission as major R.A.M.C., working there with many Bart's friends until 1917, when he left France to become president of invaliding medical boards for the Royal Air Force in England with the rank of wing commander. After the war he took up again the threads of consulting and hospital practice at the West London and the Miller Hospitals, and was elected consulting physician to the Blackheath and Charlton Hospital, and physician to the King George Hospital at Ilford. His career in civil life, already broken by four years of war, was interrupted by attacks of severe illness, and he underwent several operations, but eventually got back to full working capacity. Throughout these hard trials he maintained the courage and good humour which were part of his nature.

Dr. Pritchard joined the British Medical Association in 1910, and was honorary secretary of the Section of Medicine at the Annual Meeting in Birmingham in 1911 and representative of the Marylebone Division at the Aberdeen Meeting, which broke up on the eve of war. In later years he held office as president of the West London Medico-Chirurgical Society and of the West Kent Medico-Chirurgical Society. He was a very capable all-round physician who habitually carried out most of his own pathological and bacteriological work in private practice. Very loyal to all the institutions he served, and on friendly terms with everybody, he was diligent in attending committee meetings, where his common sense and sound judgment were valued by lay and medical colleagues. He took much interest in Freemasonry, and was a Past Master of the Rahere and Cavendish Lodges. Harold Pritchard had many devoted friends within and without the medical profession; they have lost a charming and sympathetic companion with a keen sense of fun. He is survived by his wife, whom he first met at Le Touquet when she was working there as a V.A.D., and by a daughter and a son. His happiest days were spent with his family at home or on holiday in Devonshire.

F. W. GOODBODY, M.D., M.R.C.P.

Member of Council, British Medical Association

The death of Dr. F. W. Goodbody, which took place in London on November 30 after a long illness, is an occasion of personal sorrow to many engaged in the central and metropolitan activities of the British Medical Association. He had been a member of the central Council and its committees for the larger part of two decades. His principal work was done on the Naval and Military Committee, of which he was a member from 1920 until his death, and chairman for ten years. This is a committee which does not come prominently before the general body of members, because much of its work is necessarily of a confidential nature; but those who knew what Goodbody did there, as well as on the Journal Committee, of which he was a member for twelve years, highly valued his homely wisdom, the rugged simplicity of his speech, his Irish warmth and impulsiveness, his essential modesty, and his friendliness and eagerness to help wherever help was needed.

Francis Woodcock Goodbody was born in 1870, the eighth son of Marcus Goodbody of Clara in King's County and Black Rock in County Dublin. He was educated at Brighton College and Dublin University and studied medicine at Meath Hospital. He qualified in 1894, and took the M.D. of Trinity College, Dublin, a year later, afterwards studying medicine in London, Zurich, and Breslau, before settling down in 1897 as assistant professor of Pathological Chemistry at University College, London. He held this appointment for twenty-two years. The war came towards the end of that period, and Goodbody served as captain, R.A.M.C.(T.), and was attached to the Artists' Rifles, with which he kept contact in later years. At the end of the war he served for a time as Acting Commissioner of Medical Services, Irish Region, and then returned to University College, this time as lecturer in medical chemistry. At the College as everywhere else he was a popular figure, and did much useful work as president and treasurer of the Students' Union.

Although he was not in the practice of clinical medicine, few would have suspected that his work was in the laboratory and lecture theatre, for his interest was in medicine as a whole. While holding it essential to

employ the most advanced and delicate laboratory methods, he deprecated any tendency to rely too much upon results of tests in diagnosis and treatment instead of upon the accumulated knowledge of signs and symptoms. His own excursions into medical literature were principally concerned with the chemical investigation of gastric and intestinal disease, but he acknowledged that this should play only a subordinate part, and said that he would be sorry to give a definite diagnosis of carcinoma of the stomach as a result of gastric analysis.

Dr. Goodbody joined the British Medical Association immediately on qualification and became a member of the Marylebone Division. In 1922 he was elected chairman of his Division, and in the same year honorary secretary of the Metropolitan Counties Branch. He became president of the Branch in 1926, and the unusual compliment was paid of electing him president again after an interval of five years. His second term covered the important year when there fell upon the Branch Council the arduous task of preparing for the Association Centenary in 1932. At Annual Representative Meetings in recent years he presented the report on Service matters. No civil practitioner had a more expert knowledge of conditions in the Services, and he was always zealous to secure proper status and pay for medical officers engaged with the Forces. Soon after he became chairman of the Naval and Military Committee the Warren Fisher Committee was set up, and Goodbody had most to do with the shaping of the evidence which the Association gave. The shortage of medical officers for the Services was at that time a matter of concern, and Association subcommittees were established for each of the three Services—the R.N.M.S., the R.A.M.C., and the R.A.F.—and on each of these Goodbody served for two years. It was at his instance that certain aspects of the Indian Round Table Conference affecting medical services in India were brought to the Council and a special committee appointed. He served also on the Central Emergency, Parliamentary Elections, and other committees.

He married in 1901 Olga, the daughter of the late Dr. George Harley, F.R.S. She died two years ago. A son and a daughter survive them.

NOEL DEAN BARDSWELL, M.D., F.R.C.P.

The death of Noel Bardswell closes a chapter in the evolution of tuberculosis treatment from an activity chiefly of voluntary and private sanatoria to one administered largely by the State. After graduation at Edinburgh in 1895 he became house-physician to the Royal Infirmary, Sheffield, and grew interested in the Nordrach treatment of pulmonary tuberculosis. He persuaded the authorities to set aside six beds for this purpose, and as in these early days a prominent feature of the Nordrach regime was overfeeding, Bardswell began to investigate problems of diet. This work attracted the attention of Sir James Kingston Fowler, and Bardswell, with Dr. J. E. Chapman (now of the Ministry of Health), went to London, where they carried out in the laboratory of University College Hospital work on the metabolism of Fowler's patients.

In 1901 Bardswell went to Nordrach-on-Dee Sanatorium in Scotland as second physician, and a year or two later took over from Dr. Burton Fanning the well-known private sanatorium at Mundesley, Norfolk, in association with Dr. Chapman. When in 1906, after many delays, King Edward VII's Sanatorium was opened at Midhurst, Bardswell became its first medical superintendent; this selection was the measure of his repute at that period. He was a member of the Astor Committee which reported

in 1912 and recommended the Edinburgh dispensary plan as the foundation of anti-tuberculosis measures. He remained at Midhurst, except for war services, until 1917, and on retirement was made a Member of the Victorian Order. This ended the private phase of his career, and henceforward, until the last few years, he was an official.

The London Insurance Committee had become the metropolitan authority for the treatment of tuberculosis, and Bardswell succeeded Dr. Squires as its medical adviser. In 1921 this function was merged in the London County Council, with whom Bardswell continued to serve until his retirement in 1936. He was responsible for the supervision of all the L.C.C. patients, and his period in charge of the service saw an enormous development of facilities for the treatment of London cases, not only in the county area but in institutions as far afield as Cornwall and Suffolk. On his experience at Midhurst he compiled (with Mr. J. H. R. Thompson) a statistical examination of the results of sanatorium treatment—a model for surveys of this kind—and concluded that something further was necessary than the treatment then in vogue. These adumbrations preceded collapse therapy, and Bardswell's later interest in boarding-out contact cases, the Spero workshops for tuberculous men, and other social measures against the disease, which he had first encountered in Edinburgh under Sir Robert Philip. On leaving County Hall, Bardswell undertook for the National Association for the Prevention of Tuberculosis a two-year survey of tuberculosis in Cyprus. Alarmist reports about its incidence were found to have been exaggerated, but he tested samples of the population with tuberculin, established the epidemiology in two interesting monographs, and his recommendations have been accepted by the Colonial Office. He had hoped to make further surveys of other British Dependencies in this way.

Bardswell solved the problem of mental transition from the private consultant to the public official by never undergoing it. He remained an oddly informal character, who looked and dressed like a rustic squire, and frequently wrote his letters in pencil. His nomadic instinct never died. He enjoyed his visits to Cyprus, and seemed equally at home with great officials of State, Greek physicians, Turkish healers, and village muktars. His skilful subtlety made possible the intricate social inquiries into a disease which is hidden and feared. His wife, who with four children survives him, has achieved a reputation in archaeology.

THE LATE SIR HENRY GRAY

Dr. Thomas Fraser, C.B.E., D.S.O., D.L., writes:

I was much distressed to learn from two sources in Montreal that I had perpetrated an error of fact in the obituary of Sir H. M. W. Gray written by me and published in your issue of October 15. Therein I stated that the name of Professor Archibald of Montreal appeared on the piece of plate presented to Sir Henry by surgeons who served under him in France. I can only account for this by a lapse of memory, as I last saw the plate some sixteen years ago, but I wrote what I did believing it to be true. Sir Henry was consulting surgeon to the Third Army for several years; and had I recalled that the Canadian Corps served mainly in the First Army (which I knew of as I was in that Army in charge of a casualty clearing station for six months) the implication that Mr. Archibald served under Sir Henry would not have been suggested. The time limit which is imposed on the contributor of such a notice (which is expected to appear in the next issue of the *Journal*) demands haste and dependence on memory, particularly when the death of the subject of the notice occurs in the second half of the week. In this instance

my memory has let me down. I unreservedly withdraw the statement and offer my apology to Professor Archibald for the distress it may have caused him. In the event my phrasing following the above statement was unfortunate, as it bore the possible implication that I was at least hinting at disloyalty on the part of Professor Archibald to an old chief. Such disloyalty never entered my mind. I was for over thirty-three years a member of the teaching staff of a Medical School of some antiquity, where, on several occasions during my time, a junior was preferred for a professorial post, and I cannot recall a charge of disloyalty ever being imputed under such circumstances or the bona fides of the selectors being doubted. I regret, however, that it seemed possible to draw the implication above mentioned from the words I used. Never by word or in letter to me did Sir Henry resent the appointment of Mr. Archibald to the professorship in McGill University.

Brigadier-General F. E. Burnham writes from Haley Springs, Arrow Lakes, British Columbia:

The death of Sir Henry Gray marks the passing of another of the long line of war veterans who have gone to their reward. Those who have passed on may be spared the knowledge of the futility of their sacrifices during that great struggle. On the Western Front I had no opportunity to meet Sir Henry, but was in close touch with many who had served with him. All spoke of him with admiration and affection. Sometimes one may judge a man better by what his friends say of him than from a short acquaintance. I realized that Sir Henry Gray was a great surgeon and cultured gentleman. More than that no one can say. I have always advocated that the door of Canada be kept ajar for distinguished members of the profession who might come from abroad. Any country which will now take a hundred scientists, physicians, artists, and musicians from among the refugees of Central Europe will be immensely enriched thereby. When Sir Henry Gray came to Canada I felt that it was a great advance for medical education.

THE LATE SIR ROBERT JOHNSTONE

At the meeting of the Senate of Queen's University of Belfast, on November 23, a resolution of sympathy with Lady Johnstone in the death of her husband, Sir R. J. Johnstone, was proposed by Professor W. W. D. Thomson and passed in silence. "As a rule," he said, "doctors are bad citizens inasmuch as they stand as a body aloof from civic affairs and national politics. The medical profession, however, has in every country provided men of affairs who have risen high in the council of the nation, but with scarcely any exceptions such men have found the practice of medicine incompatible with their political and public duties. Sir Robert Johnstone was an exception to this rule, and maintained the closest relations with his profession as a consulting gynaecologist, as professor of gynaecology in this University, as surgeon to the Royal Victoria Hospital and the Royal Maternity Hospital, whilst giving much of his time to the Parliament of Northern Ireland and its commissions, to the medico-political activities of the British Medical Association, to the work of the General Medical Council as our representative, to the chairmanship of the Board of Management of his old school, the Royal Academical Institution, and to the work of the Senate and its committees. Sir Robert Johnstone worked not for money, not for fame, not for award or the applause of men, but for the joy of the working. The last year of his life saw the recognition of his achievements, and honours were showered upon him—the presidency of the British Medical Association, a knighthood, the honorary fellowship of the Ulster Medical Society, and the honorary degree of Doctor of Laws awarded by this Senate, but, alas! never conferred. The mothers of Ulster loved Sir Robert for his gentle and wide humanity and for his skill in their hour of need; his students admired the deft and decisive hands which

operated so quickly and with so little shock; his colleagues were attracted by his brilliant intellect, his broad outlook and his freedom from bias, his sound judgment, his wise counsel, his sense of humour, and his wide interests. To those privileged to attend him during the last few months the unruffled calm and the dauntless courage of the man as he faced the inevitable will never be forgotten. To few men did the years of retirement present so pleasant a prospect. He was still at the zenith of his powers, congenial work was waiting for him, a beloved companion at his side, ever ready to help his leisure, to indulge his love of literature, and to ride his numerous bobbies. And yet no word of self-pity escaped his lips as he saw the 'Delectable Mountains vanish in the Mist.' . . .

"A. J. C." sends the following tribute to the memory of NEALE LEO LOCHRANE, M.D.: A year ago died a colleague and friend whose loss was too keenly felt to let it pass unnoticed by the profession he loved. Educated at Stonyhurst, Edinburgh University (where he was a boxer of some repute) and Rome, he qualified in 1912, served as H.P., H.S., and gynaecological H.S. at the Glasgow Infirmary, and took his M.D. in 1914. In August, 1914, he was attached as M.O. to the 3rd Royal Scots, and in June, 1915, he was posted to the 12th Hants Regiment on his request to be sent over-seas. Service followed in France and Salonika, where he was mentioned in dispatches for "distinguished conduct in the field." He was finally invalided home in 1918 seriously ill with malignant malaria and phlebotomus fever. After a prolonged convalescence Lochrane passed the primary examination of the F.R.C.S. and ultimately settled down in practice in Stroud, Gloucester. There he acquired a great reputation for his immense industry, keenness, and unsparing devotion to his patients. Especially was he beloved by the poor for his charitable work among them, but this was a secret he zealously guarded during his life-time. His surgical ability was recognized by his appointment as surgeon to the Stroud General Hospital, an honour which gave him great personal satisfaction. His strength sapped by the work he loved, and by his unsparing giving of himself, he developed a pulmonary neoplasm early in 1937. A very severe operation and six months of pain brought the inevitable end, but not before he gave an example of how such an ordeal should be passed through. This last trial was lightened by the most devoted nursing of his wife. Of few of us can it be said that we have hurt no one by action or word; that we have not merited rebuke or caused resentment. Leo Lochrane was such a man—unknown to the world at large, but loved by all who understood him and worshipped by those he served.

Dr. WILLIAM VALENTINE of Earlestown, Lancashire, died recently at the age of 78. He was educated at Wigan Grammar School, proceeding to Glasgow University for his medical training, and qualified in 1885 as L.R.C.P., L.R.C.S., and L.M.Ed. Dr. Valentine started professional work in Earlestown fifty-three years ago and built up a large practice by his devotion to duty, winning the esteem and affection of his patients, as shown by the crowded church at his funeral service. He held many public appointments and was the prime mover in raising a fund to build a cottage hospital in his district, and lived to see it greatly enlarged in the form of the Earlestown War Memorial Hospital. During the great war he was medical officer at the Lady Gerrard's War Hospital at Garswood Park. Dr. Valentine joined the British Medical Association fifty years ago, was an original member of the St. Helens Division, and had been chairman and a member of the Executive Committee. He was a widower and leaves a grown-up family to mourn his loss.—A. A. W. M.

We regret to record the death on November 25, at Hereford, of Dr. GEORGE AUGUSTUS TULLIS at the age of 76. Dr. Tullis was educated at the University of Edinburgh, where he graduated M.B., C.M. in 1884. He

proceeded M.D. (with honours) in 1887, and for his thesis discussed Mediterranean-gastric remittent fever. For a time he was a member of the General Council of his university. For some years Dr. Tullis was in practice at Southsea, and then, in 1906, settled in Winchester, where he became honorary physician to the Royal Hants County Hospital and medical officer to the Winchester Dispensary and to Clayesmore School. He had been a member of the Society for the Study of Diseases in Children, the old Clinical Society of London, and the Section of Disease in Children of the Royal Society of Medicine, and had acted as medical referee to several insurance companies. In 1903 he read a paper on infantile scurvy before members in the South-East Hampshire district of the Southern Branch of the British Medical Association, a report of which was published in the *British Medical Journal*. Dr. Tullis was appointed consulting physician to the Royal Hants County Hospital when he retired in 1933, and went to live at Hereford. He had been a member of the British Medical Association for fifty-four years, joining in 1885, the year after he qualified.

The death has occurred of Dr. GEORGE WILLS BLOMFIELD of Pontefract, who had practised in that town for fifty years and had been a member of the Wakefield Division of the British Medical Association for the same length of time. He was taken ill in Aberdeen while visiting a daughter and died there on November 28. A native of Hastings, Dr. Blomfield studied medicine at the London Hospital and qualified as M.R.C.S., L.R.C.P., and L.S.A.; he took the M.D. degree of Durham University in 1903. Soon after qualifying he became medical officer at Pontefract Infirmary and then started practice in the town with his brother, the late Dr. E. E. Blomfield. For the last thirty years Dr. G. W. Blomfield had been medical officer in charge of the Military Hospital at Pontefract Barracks. He was made an honorary associate of the Order of the Hospital of St. John of Jerusalem in recognition of long service as an examiner for the St. John Ambulance Association, and he had been chairman of the local Motor Ambulance Committee. He leaves two sons, both of them members of the medical profession, and three daughters.

The following well-known foreign medical men have recently died: Geh. Rat Professor RICHARD GREEFF, for many years director of the Eye Clinic at the Charité, Berlin, aged 77; Dr. JACOB HAVERSCHMIDT, formerly professor of children's diseases and director of the Wilhelmina Children's Hospital at Utrecht; Dr. ANDRÉ RICHE, a Paris alienist, aged 69; Dr. FREDERIK VOGELIUS, an eminent Copenhagen physician, aged 72; and Dr. CARLOS COMETTO, a prominent paediatrist of La Plata, aged 60.

Medical Notes in Parliament

The House of Commons this week discussed the Government's proposals for a voluntary national register and also the report on the Official Secrets Act in relation to members of Parliament.

The second reading discussion on the Cancer Bill is proposed for December 12. Dr. Elliot promised to discuss it with the Conservative Health and Housing Committee on December 7. He also arranged to confer on the same Bill that day with representatives of municipalities.

The text of the Workmen's Compensation Acts (1925 to 1934) Amendment Bill, introduced by Miss Ward and issued on December 6, contains proposals for compensation for miners' nystagmus.

There was laid on the table of the House of Commons on December 6 the Registration of Stillbirths Regulations (Scotland), 1938.

Medical Services in Air Raids

Sir FRANCIS FREMANTLE, on November 30, moved that medical services were a cardinal factor in the national preparation in case of air raids, and that a detailed and complete scheme should be planned without delay under responsible co-operation between the British Medical Association, other representatives of the medical profession and of the hospitals, and the Government Departments concerned. He said a scheme should be devised covering, first, the personnel of the medical and auxiliary services; secondly, the institutions and their equipments; thirdly, method of communication between different parts of the medical services and the civilian defence service; and, fourthly, the ambulance service for the transport of the wounded. In June of this year a special branch of the Ministry of Health was created to deal with emergency medical services, and Dr. Hebb, Director-General of Medical Services at the Ministry of Pensions, was transferred to it. This ought to have a considerable increase of staff, and much required to be done. At the request of the Committee of Imperial Defence the British Medical Association started a register of members of the profession in May, 1937. That register must be revised every year, and the Government had undertaken the cost of its revision. The result of the questionnaire issued by the Association showed that 95 per cent. of the profession were prepared to give their services in one way or another. It was agreed that Government Departments and hospitals should be staffed in case of an air raid only through and according to this register. Nevertheless irregular applications still continue to be made from some Departments.

One difficulty which arose when the crisis came was uncertainty on the actual position and equipment of, and the demands that would be made on, first-aid posts. In London, according to the Home Office, first-aid posts were not to have any medical officers. Patients would be sent on to the general hospitals, which had been cleared of ordinary patients so that they might be used as clearing stations. If there were no medical officers at the first-aid posts the casualty clearing stations would be blocked with minor cases. In an air raid, beside wounded members of the civil population there would be cases of nervous breakdown, hysteria, mania, and mental disorder with which it would be difficult to deal. Some of the primary cases would need morphine, which non-medical people could not be allowed to administer. Sir Francis was sure that the supply of medical men would suffice for first-aid posts in London, but the question was whether it would suffice elsewhere. The Home Office said the first-aid posts had nothing to do with the Ministry of Health, although that Ministry had charge of hospitals and medical personnel. Why should first-aid posts be under the Home Office when ambulances, stretcher squads, casualty clearing stations, and hospitals were all under the Ministry of Health? To these problems had been added that of evacuation.

Co-operation was needed between the two Departments and the medical profession. The position was so serious that the British Medical Association, the Royal College of Physicians, and the Royal College of Surgeons sent a joint deputation to the Minister for Co-ordination of Defence on November 8. A full statement put before the Minister by Sir Kaye Le Fleming showed that the British Medical Association had established a central emergency committee representative of every branch of medical practice for the supply of medical services. They still required co-ordination of the actual demand, and the Minister promised that this would receive consideration.

The medical officer of health was commonly forgotten when considering medical services, especially in the countryside. He was responsible for the services in schools and in county hospitals and for the whole Poor Law system. These would be much affected by air raids. The medical officer for one county recently had to close a village school because of a virulent outbreak of diphtheria, yet he was informed that one hundred children were to be evacuated from that village. According to the air raid handbook the medical officer of

health was the controlling official of first-aid parties, first-aid posts, and ambulances, in addition to his ordinary work. What was his status in regard to voluntary hospitals and to municipal and auxiliary hospitals? What was the position in connexion with the St. John Ambulance Brigade and the Red Cross Societies? The Committee on Evacuation, presided over by Sir John Anderson, in its report made in July devoted only two lines to health services. Nurses, dispensers, laboratory workers, clerks, stretcher-bearers, and messengers would all have to be brought in with proper organization, and if during an air raid telegraph wires and telephones were broken down special communication must be organized for the medical services.

THE POSITION OF HOSPITALS

Sir HENRY MORRIS-JONES seconded the motion. He asked if the first-aid posts in London were to be in trenches in the parks or in annexes to the big hospitals, or where they ought to be—in concrete underground shelters. In London, he understood, fifteen voluntary hospitals and nineteen municipal hospitals had been earmarked for casualty clearing stations. A large number of voluntary hospitals, including some big teaching hospitals, tuberculosis hospitals, children's hospitals, and maternity hospitals, were to carry on as usual. He hoped that hospitals in London of whatever kind, unless clearly outside the radius of possible bombardment, would evacuate all the sick to their homes or to hospitals in the country. The boards of management of hospitals were seriously concerned about their position. Were preparations being made to have underground operating theatres in the clearing hospitals? The question of finance required attention. Many orders given by hospitals in the last crisis were without legal sanction, and King Edward's Hospital Fund for London had made a distribution of £100,000 in advance of this year's grant. Were the hospitals and the country adequately equipped for an emergency in drugs, dressings, blankets, etc.? Thousands more stretchers were required, and these should be of a uniform pattern. Motor-ambulance drivers should be trained to drive with gas masks on and lights dimmed. More use should be made of water transport on the Thames and the canals. The staffs of hospitals should know whether they would be wanted in hospitals, in the territorial service, or in their own civilian occupation. There should be a mobilized force of doctors for transfer to any centre which had suffered intensive bombardment. Were medical students to be kept in London or sent to the country to become fully qualified?

Dr. EDITH SUMMERSKILL said that in the last crisis she found many cases of hardship among patients who were evacuated from casualty clearing hospitals and sent to their homes. Hospitals should be built in the country immediately or buildings should be earmarked for patients. The Home Office or the Ministry of Health had made the fantastic suggestion that tents should be used as casualty hospitals, but the British Red Cross in Abyssinia had pointed out that tents were a favourite target and that there would be no protection against splinters, gas, or blast. In one hospital in London with 2,000 beds 400 people were expected to be brought in every hour when the crisis came. That hospital found great difficulty in obtaining instruments, cotton-wool, dressings, and morphine. They wanted half a ton of plaster-of-Paris for treatment of fractures, but could only obtain 2 cwt. That hospital could not get splints, so the medical superintendent set the staff to work sawing boards to make them. There was also a lack of bleaching powder.

GOVERNMENT REPLY: REGIONAL ORGANIZATION

Mr. BERNAYS, replying for the Government, said Sir Francis Fremantle had inaugurated a most valuable debate. The Government had a plan for the expansion of the medical services in time of war. It was a regional organization for dealing with casualties on the basis of first making beds available in existing institutions and then expanding by means of satellite annexes. There were registers of doctors and of nurses and a scheme for filling all needs from those registers on a unified basis. The Ministry of Health was at work on further plans which would form the basis of regional discus-

sion. If war had come medical personnel would have been directed, through the Central Emergency Committee of the British Medical Association, to places where the needs were greatest. The register compiled by the British Medical Association was a file, not an order to move. It was impossible to give the order to move until the air raids began. At the outbreak of war the best place for a doctor was with his own patients, and the most obvious air-raid dressing station was a doctor's own consulting room. It was most important to avoid immobilizing doctors by concentrating them in one place before there was actual need for their services. Proper co-operation was most important, and a big step had been taken towards it by arranging that not all the Territorial Army hospitals originally designated would be mobilized at the outbreak of war. That would make hundreds of doctors and nurses available for the treatment of civilians. Sir John Anderson was giving attention to the question of the requirements which might be conflicting. With regard to nurses arrangements were made during the crisis to put hospitals in touch with the local nursing organizations, but more complete organization was necessary and a central register was being established of nurses and nurse auxiliaries who would be available in time of war. A plan was under consideration for recruitment of additional nurses and for training girls to do first-aid work.

The Government was conscious of the need for expanding the potential hospital service, and as a preliminary had surveyed existing hospital accommodation in England and Wales. A similar survey was made in Scotland. If hostilities had started there would have been 150,000 beds available for air-raid casualties, and at the end of a fortnight that number would have increased by 100,000. The Home Secretary appointed a committee of medical experts under the chairmanship of Sir Charles Wilson to consider what was required for the casualty organization in the London area. Its conclusions were embodied in a circular which was sent to every county council, county borough council, and voluntary hospital authority in the country informing them that every hospital must be ready to clear as many beds as possible on receiving warning that an emergency had arisen, and also must prepare schemes for expanding their hospital accommodation. Later the Ministry of Health made direct contact with hundreds of hospitals. The Ministry could not allot a precise part to every one of the 3,000 hospitals in the country, but it intended to work out a detailed war book or scheme of operations with which the hospitals could conform.

DOCTORS TO STAFF AIR-RAID POSTS

He appreciated the importance which was placed upon air-raid posts. The Ministry of Health had now been given responsibility for those posts and also for the ambulance services, and it was the policy of his Department that every air-raid post should be staffed by a doctor. The best man for the post was probably the man in a local practice in the area where the post was established. He was not in a position to reply to-night to the question whether air-raid posts would be in underground shelters. A circular dealing with these questions would shortly be issued to local authorities. Local authorities would continue to be responsible for preparing schemes for ambulance organization and also for first-aid posts, but the Ministry would see that these were complementary to the hospital service and that the first-aid posts were placed and designed to relieve the hospitals so far as possible.

In additional equipment the Ministry had ordered 50,000 beds and mattresses and 90,000 stretchers. They expected final deliveries in a few weeks. The London County Council had been authorized to spend £4,000 in providing ten of their large fever hospitals with surgical equipment, and the question of difficulty in getting necessary medical requisites was actively in hand in his Department. The majority of stores could be used in the future and did not involve a loss. The Ministry of Health would consider exceptional claims for loss if the voluntary hospitals would make these. He gave details of preparations made to evacuate patients from London from the general hospitals, and said they were to be removed to smaller towns approximately fifty miles distant.

HOSPITAL ACCOMMODATION

Hospital officers had been reviewing the hospital accommodation in their regions to determine where it must be increased and improved. The next step was for hospital officers to get into touch with all hospital authorities and agree what part they would be expected to play. Local discussions had been arranged, and it was hoped shortly to arrange regional conferences at which proposals could be considered with the hospital authorities and representatives of the medical profession. As soon as plans were settled equipment would be distributed and work undertaken to improve facilities. The next stage would be to consider what was required in completely new hospital accommodation. A decision had not yet been taken on the use of tents.

He agreed with Sir Francis Fremantle on the importance of medical services in civil evacuation and that a strain would be thrown on medical services in the receiving areas. The Department would seek the assistance of the medical profession in considering what emergency services must be provided. The Society of Medical Officers of Health was formulating suggestions. It would be necessary to concert plans with the British Medical Association for transferring doctors to country districts where an influx of new patients called for the strengthening of the medical organization.

Captain ELLISTON said the compilation of the register by the British Medical Association was an act of great patriotism. If great masses of the population were to be evacuated they must take their doctors with them. He hoped they would avoid the mistakes of the last war, when leading consultants, instead of becoming consultant physicians in military hospitals, did what was almost first-aid work at the front. He was sure that if the British Medical Association was responsible for the arrangements to use the services of medical men to the greatest advantage steps would be taken to protect the practices of doctors who went on active service.

The resolution proposed by Sir Francis Fremantle was then carried unanimously.

Hospital Service in Air Raids

In the House of Lords on December 1 LORD GREVILLE called attention to the hospital service of London in an emergency, and moved a resolution calling for a detailed scheme to be drawn up and issued to hospitals, giving exact instructions on what steps should be taken in case of air raids. He said that the question of air-raid precautions and the treatment of casualties had been under consideration for some two years, and the voluntary hospitals, through the Voluntary Hospitals Association, had endeavoured to get some information from the Government Departments on the subject. If there had been a little less secrecy and a little more consultation in the past few years a great deal of the rush and expense of a few weeks ago would have been avoided. The hospitals had never really had a chance of expressing an opinion on the Government's scheme, and had not yet been asked to express one. He thought that fundamentally parts of the scheme were wrong. He did not think it was right to fill the London hospitals with all the leading surgeons in the profession. London would become a front-line trench, and, therefore, totally unsuitable for collecting large numbers of casualties within its borders. He hoped that the Home Office, the Ministry of Health, and the authorities concerned with the evacuation and treatment of the wounded would really consult the hospitals a little more and give serious consideration to the question of the overcrowding of London hospitals.

VISCOUNT GAGE, replying for the Government, said it had been freely admitted that the crisis did catch the Government incompletely prepared in several directions. Having recounted what had been done and what the hospitals had been told, he added that there were matters on which the Government was in considerable difficulty. On the question of medical staff, owing to their long training, the number of qualified doctors in the country could not suddenly be expanded, even if the services of some of the advanced medical students were utilized. As opposed to the last war there were two entirely

new medical problems. First, they had not only the service needs to think about, but the additional needs of these areas in which the evacuation of London generally was to take place; and, secondly, there was the question of air-raid casualties in London itself and elsewhere. Not unnaturally there was considerable divergence of expert opinion as to the extent of the medical demands that these casualties would make, and that must really depend on events. There were only two certain principles to guide them—first, that every doctor in the country must be employed to the best possible advantage, and, secondly, that the doctors must possess a considerable element of mobility. He could not say that the plans for the proper utilization of medical staff had even now been worked out completely, but they were being worked out and, had the crisis developed, the registers already in the possession of the British Medical Association would, to a large degree, have prevented unnecessary waste of effort. The organization of mobile medical units had already begun. In the course of a few weeks all the hospitals would be visited, detailed plans would be agreed with them, and they would know exactly what their task would be. He understood, though he could not give a precise answer, that the question of the evacuation of hospital patients was being considered.

The motion was withdrawn.

Criminal Justice Bill

In the House of Commons on November 29 Sir SAMUEL HOARE moved the second reading of the Criminal Justice Bill. He said that in almost all cases imprisonment was the worst possible way of dealing with uncontrolled, objectionable, and sometimes dangerous young people. Prison, particularly for short sentences, often turned them into little heroes. It made a dangerous break in their lives and gave them no training for the future. One of the main objects of the Bill was to effect an immediate reduction in the number of young persons received into prison and to provide for the ultimate abolition of imprisonment as a method of treatment for young offenders convicted for such offences as were dealt with by courts of summary jurisdiction. It was proposed to raise the age to 16, below which no child could be sent to prison after conviction; that in future no young person between 16 and 17 could be sentenced to imprisonment without a certificate from the court that the young person was of a depraved and unruly character; and that no summary court should send to prison anyone between 17 and 21 unless a careful investigation had been made into the individual case.

REMAND CENTRES

They proposed a series of new institutions for dealing with the young. For the young before conviction there would be two kinds of remand homes. The first would be for children under 14, to deal with the problem cases, the abnormal cases, which needed careful medical investigation and often mental treatment. There would also be remand centres for young persons between 17 and 23, where, again, there would be opportunities for the investigation of problem cases at older ages, and also the kind of mental investigation, in certain cases, as in the remand homes for the younger children.

MENTAL TREATMENT FOR OFFENDERS

The Bill also contained provisions for making it easier to provide medical examination and mental treatment for the old offender. Where the old could not afford to pay there was a provision under which funds could be provided by the State, though where the offender could afford to pay the sum would be recovered from him. It was proposed to transfer the Criminal Lunatic Asylum of Broadmoor from the direct control of the Home Office to that of the Board of Control. This change was not being made because there was any fault to find with the administration of Broadmoor, but because they felt that, with the growing development of this branch of medical science, it was better to bring all the mental institutions under a single control. The power of release, as was inevitable, would remain in the hands of the Home Secretary.

They were abolishing the anomalous description "criminal lunatic." He had never thought that there was any justifica-

tion for a description of that kind, for the essence of crime was that a man or woman must know what he or she was doing, and, in the nature of things, a lunatic could not be responsible for his actions. Accordingly, in future, Broadmoor would be called the State Mental Institution, and the inmates State mental patients. They had accumulated a considerable body of evidence on this side of penal treatment. They had had in progress in recent years a very scientific investigation into a number of cases of young offenders in Wormwood Scrubs. He hoped to be able to publish the report in the immediate future, but the conclusion which it reached was that here again it was dangerous to generalize and to regard mental treatment as a panacea against all sorts of evils, but that in a number of selected cases, particularly in the cases of the young, it undoubtedly did good. They felt that the time had come to make these proposals for a definite step forward along this line of alternative treatment in dealing with offenders, and particularly young offenders.

ABOLITION OF CORPORAL PUNISHMENT

He was attempting to approach these problems from the angles of prevention and reformation. In such a scheme there was no place for the remnants of a period which looked at crime principally from the angle of retribution and deterrent punishment. He therefore proposed to sweep away the remnants of former dispensations, now little more than the stage properties of Victorian melodrama—penal servitude, hard labour, ticket of leave, and the name "criminal lunatic." The Bill contained a provision to enable them in the future to do away with the Prison Commissioners and to merge the prison administration in the general administration of the Home Office. Consistently with this attitude he was proposing the abolition of corporal punishment except for cases of mutiny and gross assault in prisons, which were very rare, a year or even two passing without a single case. He proposed the abolition of corporal punishment because it was out of date and did not deter the particular individual on whom it was inflicted from offending again or protect society from similar crimes in future. The Cadogan Committee had come unanimously to the conclusion that the time had arrived for abolition.

SUPPLY OF PSYCHIATRISTS IN THE PROVINCES

During the debate Mr. BLINSON said he was very pleased that power was taken in Clause 19 to supply mental treatment for those delinquents who required it. He was afraid that the Home Secretary's advisers, living and working in London, might not realize how difficult that clause would be to work in the provinces unless the Home Office took very strong steps and supplied plenty of initiative. There was any number of highly trained psychiatrists and specialists in London, but the whole of the provinces were an absolutely arid waste so far as they were concerned. They might get an odd psychiatrist in large towns like Manchester or Liverpool, but there was nothing like the supply of trained doctors in the provinces that there was in London. Clause 19 could not be worked unless the Home Office was prepared to take steps to supply that shortage, the reason for which was obvious. These were specialists, and specialization in practice generally depended on hospital work in the towns where the practice was. It was very difficult for a London-trained specialist to go, say, to a northern town or outside London and build up a practice, and until some steps were taken to enable London-trained doctors to do so there would not be the supply of psychiatrists required if the Bill was to work properly.

There were methods by which this difficulty could be overcome. There were a number of child guidance clinics up and down the country, some of which already had psychiatrists, generally part-time, and the psychiatrists themselves were attempting to build up a practice in the towns while they were working for the child guidance centres. A number of other child guidance clinics would have part-time specialists if they could afford them. If the Home Office was prepared to co-operate wherever possible with child guidance clinics and with progressive education authorities for the provision of

this service a great deal could be done at a not overwhelming expense. He gathered from the Bill that psychiatric training was to be provided at the State remand centres wherever there was one, and these centres, he thought, could be made the nucleus for the development of psychiatrist services on a far wider scale than the remand centres themselves. He hoped that there would be a number of these centres in the provinces, but there would not be one in every small town. They should utilize the trained doctors in these remand centres, use them as travelling psychiatrists to go from court to court, or to beat the service of any court within a given area, again co-operating with child guidance clinics and education committees, and all the time trying to establish part-time services.

After further discussion the debate was adjourned to December 1.

The debate was resumed on December 1. Sir ALFRED BEIT said that a complaint which he thought was justified was of the difficulty of access to medical opinion other than that of the prison doctor. In some cases these doctors were first-rate men. Nobody could deny, having seen the hospital at Wormwood Scrubs, that they had built a first-class establishment complete with operating theatre at that prison, but prison doctors varied in knowledge and in quality, and they sometimes gave him the impression of reluctance to consult outside doctors.

Mr. GEORGE LLOYD said that the Home Office was investigating better ways of serving food in prison, and hoped to tackle more scientifically the question of diets a little later. An independent medical opinion was rarely asked for, but it was granted in proper cases.

The Bill was read a second time and sent to a standing committee. The financial resolution in connexion with the Bill was also agreed to in committee.

Summary of Cancer Bill

Dr. ELLIOT, supported by the Secretary of State for Scotland and other Ministers, presented the Cancer Bill on November 30. The Bill's full title is "A Bill to make further provision for the treatment of cancer, to authorize the Minister of Health to lend money to the National Radium Trust, to prohibit certain advertisements relating to cancer, and for purposes connected with the matters aforesaid." The first clause states that it shall be the duty of every county and county borough in England (in Scotland of every county and large burgh), either singly or in regional groups, to secure adequate facilities for the diagnosis and treatment of persons suffering, or suspected to be suffering, from cancer, and to submit within one year from the commencement of the Act or such longer period as the Minister may allow arrangements which shall provide: (1) facilities for the diagnosis of cancer; (2) facilities for treatment either in hospitals maintained by local authorities or in voluntary hospitals; (3) for the payment in such cases as the council considers necessary of all or any travelling expenses (including the travelling expenses of a companion) reasonably incurred by persons for the purpose of availing themselves of the services provided under the arrangements; (4) for such other matters as appear incidental to or consequential on the arrangements for the treatment of cancer.

CONSULTATION WITH HOSPITALS AND DOCTORS

Before submitting its arrangements to the Minister each council shall consult, first, the Radium Commission; secondly, representatives of the governing bodies and the medical and surgical staffs of the voluntary hospitals providing services in or for the benefit of its area; and, thirdly, such local organizations of registered medical practitioners as the council considers to represent the opinions of such practitioners practising in its area. The Minister may approve with or without modifications the arrangements submitted to him by a council, and it will then be the duty of the council to carry these into effect. From time to time, or when required by the Minister, the council may make and submit to him alterations or extension of the arrangements.

A special proviso reads: "Nothing in this section shall authorize the establishment by any council of a domiciliary service by medical practitioners."

Certain sections of the Public Health Act, 1936, and the Public Health (London) Act, 1936, are made applicable to the new service, which will (*inter alia*) enable the local authority to recover the expenses of treatment in suitable cases. In Scotland such recovery will be possible under the Local Government (Scotland) Act, 1929. The Minister may require two or more councils to combine to such extent and on such terms as he may, in default of agreement between the councils concerned, direct. A joint board or joint committee discharging the functions of two or more councils shall have power to appoint such persons as it thinks fit to be additional members of the board or committee.

The memorandum attached to the Bill declares that its purpose is to establish a cancer service under which, in every part of the country, modern facilities for diagnosis and treatment of cancer will be available. At the present time, the memorandum continues, such facilities exist in some voluntary and in some municipal hospitals, but in many areas the provision is far from adequate. Semi-officially it has been explained that centres with teams of specialists and clinicians will be established for the diagnosis of patients submitted to them through the councils or practitioners or who may offer themselves for examination.

PURCHASE OF RADIUM AND CYCLOTRON APPARATUS

Clause 2 of the Bill provides for an Exchequer grant approximately equivalent to 50 per cent. of the total additional expenditure incurred by local authorities. It is explained semi-officially that in poorer localities the percentage of this grant will be considerably higher.

Clause 3 authorizes the Minister to lend up to £500,000 to the National Radium Trust for the purchase of radium and other radio-active substances and of equipment for radio-therapeutic treatment. No money is to be lent for this purpose after ten years from the commencement of the Act. It is explained semi-officially that loans will be available for purchasing deep x-ray apparatus and cyclotron apparatus, which will probably be retained centrally and lent as required. In anticipation of the passage of the Bill a contract has been made for the purchase of radium from Canada.

ADVERTISEMENT BAN

Clause 4 prohibits under penalty—in the case of first conviction a fine not exceeding £50, and in the case of subsequent conviction a heavier fine or imprisonment—the publication of any advertisement (a) containing an offer to treat any person for cancer or to prescribe any remedy therefor, or to give any advice in connexion with the treatment; or (b) referring to any article or articles of any description manufactured, produced, imported, sold, or offered for sale in terms which are calculated to lead to the use of that article or articles of that description in the treatment of cancer. A proviso is added that it should be a valid defence in any proceedings under the clause to prove that the advertisement was published only to registered medical practitioners, registered nurses, registered pharmacists and authorized sellers of poisons, persons undergoing training with a view to becoming registered in these occupations, or persons carrying on a business which includes the sale or supply of surgical appliances. It is also provided that it shall be a defence to prove that the advertisement was published only in a publication of a technical character intended for circulation mainly among persons of the classes mentioned above. It is further provided that the section shall not apply to the publication of an advertisement by a local authority or by the governing body of a voluntary hospital. The term "advertisement" in this section includes any notice, circular, label, wrapper, or other document, and any announcement made orally or by any means of producing or transmitting sounds.

The financial memorandum to the Bill states that "it is not possible at present to forecast accurately what the total additional expenditure on account of the new service will be, but

on such statistics as are available and on the assumption that existing facilities for diagnosis and treatment remain undiminished it is estimated that when this service is in full operation the additional expenditure will amount to approximately £600,000 a year for England and Wales and £100,000 for Scotland." It is proposed that the moneys to be advanced to the National Radium Trust shall be repayable to the Minister with interest by annuities spread over appropriate periods. The additional staff required by the Ministry of Health and Department of Health for Scotland by reason of the Bill will, it is estimated, cost about £2,500 a year in the earlier stages after the Bill becomes law and somewhat less in later years.

Mr. Chamberlain announced on December 1 that the second reading of the Bill and consideration of the necessary financial resolution would be taken on December 6, but this second reading was subsequently postponed to allow local authorities further time for examining the financial provisions.

Pasteurization of Milk

Professor W. W. Jameson and Professor G. S. Wilson of the London School of Hygiene addressed the Conservative Health and Housing Committee on November 30 on the scientific evidence in support of the pasteurization of milk. At the close of the meeting the chairman (Sir Francis Fremantle) was asked to report the following resolution to the Prime Minister:

That in view of the consensus of scientific opinion, this committee thinks it desirable that the councils of urban areas with a population of not less than 40,000 should be given the power to enforce pasteurization of all milk supplies.

Register of National Voluntary Service

Announcing on December 1 a decision to compile registers for national voluntary service, Sir JOHN ANDERSON said there would be registers of all volunteers enrolled for the various reserve, auxiliary, and civil defence services, registers of those earmarked as reserves for the different services, and a register of the unallocated reserves. Arrangements were being made for the compilation of separate registers of persons possessing exceptional professional or technical qualifications; many scientific and technical institutions had already taken steps to compile such registers, and these would be available. These registers, with the records already available of men included in a special list of vital occupations, would constitute the National Voluntary Register. If this country became involved in war a complete national register would be necessary, and to ensure completeness it would have to be compiled under compulsory powers. Such a register would not only be of great value in connexion with a scheme of food rationing, but would enable the whole of the national resources both of manpower and woman-power to be marshalled and conserved for a conflict which might be prolonged.

Employment of Medical Refugees

Mr. GARRO JONES, on December 1, asked Dr. Elliot to consider the establishment, in co-operation with local authorities, voluntary organizations, or otherwise, of hospitals and clinics to be staffed by medical and other refugees and placed in areas where specialist and general facilities for treatment of disease are inadequate. Dr. ELLIOT replied that responsibility for health matters was by statute entrusted to local authorities, who had power to provide institutional accommodation. The employment of personnel was at the discretion of the local authorities, and he did not think it would be possible for him to take steps as suggested.

Medical Students' Instruction in Obstetrics

Sir JOSEPH LEECH asked on December 1 whether, to reduce maternal mortality, the Ministry of Health was taking steps to require that a higher standard of gynaecological tuition be given to medical students "so that inexperienced midwifery need no longer be permitted by the licensing authorities." Dr. ELLIOT said that the Interim Report of the Departmental Committee

on Maternal Mortality had been transmitted officially to the General Medical Council with special reference to the education of medical students in obstetrics. Since that correspondence the resolutions of the Council in regard to professional education which related to instruction in midwifery, etc., had been revised on November 24, 1932, and on May 29, 1936, with effect from November 1, 1938. The standard both for medical students and for midwives was being steadily raised.

Health Services in Northern Rhodesia.—Mr. MALCOLM MACDONALD announced on November 23 that additional provision for health services would be made in the 1939 Estimates of Northern Rhodesia. A disease survey of the territory was being undertaken, and campaigns initiated against syphilis, yaws, and skin affections. Proposals put forward by Sir Alan Pim and Mr. Milligan for extension of the Northern Rhodesia health services were receiving consideration.

Dental Benefit.—Asked by Mr. DAVID ADAMS on November 24 to take steps to graft on to the health insurance system a scheme of statutory dental benefit under which such treatment would be as freely available as medical benefit. Dr. ELLIOT replied that provision of dental benefit as a statutory benefit available to all insured persons would require an increase in the weekly rates of contribution at present paid by insured persons and their employers. The proposal could only be considered, when the time was opportune, in relation to demands for other major extensions of the national health insurance and contributory pensions schemes. In the meantime dental benefit must remain an additional benefit available only to the members of those approved societies which devoted part of their surplus funds to its provision.

"Iron Lungs."—Sir ROBERT YOUNG asked on December 1 whether the Minister of Health was in a position to increase the number of "iron lungs" in this country. Dr. ELLIOT, in reply, mentioned the offer of Lord Nuffield to supply these appliances gratuitously to all hospitals in the country which required them. He expressed his appreciation of this generous action. Sir FRANCIS FREMANTLE pointed out that a cheaper apparatus for the same purpose was constructed from rubber and other materials.

Tuberculosis in Wales.—The report of the Committee which investigated the problem of tuberculosis in Wales has been received, and will be published as a Parliamentary paper.

Medical News

A meeting of the Harveian Society of London will be held at 26, Portland Place, W.C., to-day (Friday, December 9), at 8.30 p.m., when Sir Alfred Webb-Johnson will deliver his presidential address on "The History of Surgery in London."

Dr. Leonard Colebrook will give a Chadwick Public Lecture on "The Control of Puerperal Fever" on Tuesday, December 13, at 5.30 p.m., at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., with Dame Louise Mellroy in the chair.

The Benjamin Ward Richardson Lecture on "The Hygienic Treatment and Disposal of Offal and By-products in Abattoirs" will be delivered by Mr. John Austin at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on Tuesday, December 13, at 5.30 p.m.

The annual dinner of the Medico-Legal Society will be held at the Connaught Rooms, Great Queen Street, Kingsway, W.C., on Friday, December 16, at 7.15 p.m., with the president, the Hon. Mr. Justice Humphreys, in the chair.

A meeting of the Illuminating Engineering Society will be held at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, S.W., on Tuesday, December 13, at 7 p.m., when Mr. W. D. Wright, D.Sc., will read a paper on "The Response of the Eye to Light in Relation to the Measurement of Subjective Brightness and Contrast."

In our advertisement columns this week the Southern Rhodesian Government Service invites applications for a pathologist for appointment as Director of a Public Health Laboratory in Southern Rhodesia. The salary is £1,000 per annum, rising by annual increments of £50 to £1,250. Applications are also invited by the Board of Control for a Commissioner on the Board's Staff at a salary of £850 per annum, rising to £1,180.

A meeting of the Pharmaceutical Society of Great Britain will be held at 17, Bloomsbury Square, W.C., on Tuesday, December 13, at 8.30 p.m., when Mr. W. G. Templeman will deliver a lecture on "Plant Growth Hormones and their Uses."

A sessional meeting of the Royal Sanitary Institute will be held at Leicester Town Hall on Friday, December 16, at 5 p.m., when discussions will take place on "The Progress of Cremation," to be opened by Dr. E. K. Macdonald, and on "Ministry of Health Model Series IV, Building By-laws (1937): the Problem of Revision of Existing By-laws," to be opened by Mr. Harold Webster.

The annual general meeting of the Jewish Health Organization of Great Britain will be held at 19, Rampart Street, E., on Sunday, December 11, at 3 p.m., when Dr. J. Alison Glover will give an address.

The Lausanne Medical Graduates' Association held a luncheon and meeting on November 24 at the Langham Hotel, London, the president for 1934-8, Dr. D. A. Imrie, being in the chair. There were three toasts: The King; the University of Lausanne and the L.M.G. Association; and Our Guests and Visitors. Dr. F. W. Crossley-Holland replied on behalf of the guests. Dr. H. W. Abbott was elected president for 1938-42, and Dr. C. T. Gasking president-elect for 1942-6. Laudatory remarks and many expressions of gratitude for help given by the hon. secretary, Dr. C. A. H. Franklyn, were made by Drs. Abbott, Bellamy, Gasking, and Imrie. The hon. secretary then presented his report and financial statement, and Dr. Robert Fleming was appointed a vice-president.

The House of the British Medical Association, including the Library, will be closed for the Christmas holiday from 5 p.m. on Friday, December 23, to 9 a.m. on Wednesday, December 28 (Library 10 a.m.). Owing to the holiday the *Journal* for December 24 will go to press on Tuesday, December 20, and all editorial communications and advertisements intended for that issue should reach the Editor and Advertisement Manager respectively by the first post on Monday, December 19, at the latest. Material for the issue of December 31 should reach the Editor or Advertisement Manager by the first post on Friday, December 23.

Sir Milsom Rees is again offering two £100 scholarships at Port Regis Preparatory School to the sons of medical men. Candidates must be under 9 years of age when the examination is held during the first week in March, 1939. Applications should be addressed to the Headmaster, Port Regis, Broadstairs.

From December 17 the address of the Health and Cleanliness Council will be Aldwych House, Aldwych, W.C.2.

Mr. Howard Stevenson, surgeon to the Royal Victoria Hospital, Belfast, was returned unopposed on December 5 as Unionist M.P. for Queen's University in the by-election caused by the death of Sir Robert Johnstone, former President of the British Medical Association.

The Lord Chancellor has added the name of Mr. Gerald S. Hughes, M.B., B.S.Lond., F.R.C.S., to the Commission of the Peace for the City of York.

The Water Examination Department of the Metropolitan Water Board has been transferred to the Board's new laboratories at 177, Rosebery Avenue, E.C.1 (telephone: Terminus 3300), to which address all communications should be sent.

Dr. Patricia H. S. Shaw and Dr. J. E. Outhwaite (Middle Temple) and Dr. T. L. Hughes (Gray's Inn) were called to the Bar on November 17.

Professor Émile Sergent of Paris has been made Commander of the Order of Leopold of Belgium.

EPIDEMIOLOGICAL NOTES

Acute Poliomyelitis

The incidence of poliomyelitis in England and Wales continues to fall, though a slight increase was recorded in London. The chief counties affected were London 7 (Deptford 2; Battersea, Bethnal Green, Camberwell, Greenwich, and Hammersmith 1 each); Glamorgan 6 (Cardiff 4, Swansea 1, Pontardawe 1); Essex 4 (Chelmsford rural 2, Braintree and Bocking 1, Harwich 1); Lancaster 4 (Liverpool 3, Southport 1); Derby 3 (Long Eaton, Ashbourne, and Bakewell 1 each); Southampton 3 (Southampton, Eastleigh, and Hartley Wintney 1 each). There were three cases in Edinburgh.

Enteric Fever

In England and Wales notifications of enteric fever fell from 31 to 21 and in London from 11 to 9, but in Eire an increase from 5 to 10 was recorded. The chief centres affected were London 9 (Shoreditch 5, Hampstead 2, Chelsea and Islington 1 each); Middlesex 3 (Wembley 2, Ruislip-Northwood 1); Anglesey 2 (in Aethwy). Of the 9 typhoid fever cases in Eire 4 were in Tralee, 2 in Waterford, and 1 each in Castletown (Cork), Dublin, and Sligo. One case of paratyphoid fever was notified in Dublin. The Shoreditch outbreak began on November 8, and 1 patient has died. At the time of going to press 2 further cases have been notified in the Borough of Shoreditch, making a total of confirmed cases of 25 in the borough and 5 outside the borough but probably connected with the borough cases.

Survey of Diphtheria in 1938

The provisional data on diphtheria in 1938 furnished to the Health Section of the Secretariat of the League of Nations indicate that diphtheria is on the increase in the U.S.A. and in Europe, with the exception of the Scandinavian countries and in Eastern and South-East Europe. In the U.S.A. and in England and Wales the expected seasonal increase is earlier in its appearance than in 1937. In the former country 19,307 cases were reported in 1938 up to October 8, compared with 16,554 during the corresponding period in 1937, while in the latter comparative figures are 54,490 in 1938 and 48,926 in 1937. In Germany 130,600 cases were reported up to November 8, compared with 123,389 in 1937. In France 14,145 cases were notified during the first nine months of 1938, as compared with 13,322 during the similar period of 1937. Increases were also reported in Belgium, Czecho-Slovakia, Holland, and Italy. The decline of diphtheria in 1938 compared with 1937 amounted to 50 per cent. in Sweden, 34 per cent. in Denmark and Finland, 20 to 23 per cent. in Hungary, Yugoslavia, and Bulgaria, and 14 per cent. in Poland.

Typhus in Morocco

The epidemic of typhus in Morocco which started in October, 1937, to which reference has been made at intervals in these notes, has not yet abated despite the measures taken to control the disease. It is difficult to obtain exact figures of incidence, but unofficial estimates put the number at 30,000 cases with 4,500 deaths among natives. Official figures are available for Marrakesh and district; the latest report puts the number as 4,215 cases with 474 deaths among natives and 174 cases with 50 deaths among European residents. Extensive use was made of the Blanc vaccine in prophylaxis: immunity was conferred on some 85 per cent. of persons inoculated, while in the remainder the majority had the disease in a mild form. Those who had an unmitigated attack did not establish foci of infection in communities which had been partially immunized. Areas in which Blanc vaccination had been carried out in 1925 remained free from the disease. Although no fatalities were recorded, the vaccine

produces severe reactions, especially in Europeans. Weigl preparation was used for vaccination of a few private European residents, but no conclusive evidence is available of the degree of immunity conferred.

Quarterly Returns of Births and Deaths

ENGLAND AND WALES

Births.—In the third quarter (ended September 30) of 1938, 158,228 live-births were registered, or 362 less than the number recorded in the corresponding quarter of 1937, corresponding to an annual rate of 15.3 per 1,000 of the estimated mid-year population of 1937. Though the number registered is less than that for 1937 it is higher by over 5,000 than the average figure for the third quarters of the preceding five years. Of the total births 6,471 (4.09 per cent.) were illegitimate, 132 in excess of the figure for 1937: 6,033 stillbirths were recorded (3.7 per cent. of the total births registered), 33 more than in the third quarter of 1937.

Deaths.—Deaths at 102,602 were 16,575 less than in the preceding quarter but 2,301 more than in the corresponding period of 1937. Infant mortality was 41 per 1,000 registered live births: this rate was 6 per 1,000 below the average of the ten preceding third quarters. The highest death rates from influenza, 0.13, were recorded in Blackpool, Dudley (Lincoln), and Stretford, and in Stockton-on-Tees 0.12. A death rate of 0.79 from diphtheria was recorded at South Shields, where the disease was epidemic during 1937. References to the prevalence and severity of diphtheria in South Shields and the measures undertaken to combat it have been referred to previously in these notes. Other high deaths from diphtheria were recorded in Chester 0.36, St. Helens 0.30, Barking 0.26, Stanley (Durham) 0.23, and Barnsley 0.22. Death rates from measles were 0.07 in Blackburn, Kingston-upon-Hull, Stoke-on-Trent, and Swindon, and 0.06 in Barrow-in-Furness and Stockton-on-Tees. Higher rates were recorded for whooping-cough: 0.18 in Tynemouth, 0.12 in Bath, and 0.09 in Kingston-upon-Hull. The highest death rates for diarrhoea and enteritis among children under 2 years of age were in Mitcham 34.5, Portsmouth 24.5, Heston and Isleworth 23.9, Brentford and Chiswick 21.7, and Oxford 20.1. The natural increase of population was 55,626, compared with increases of 55,432, 55,661, and 58,289 in the corresponding quarters of 1935, 1936, and 1937 respectively.

SCOTLAND

Births.—At 21,417 births were 2,582 fewer than in the preceding quarter, the rate 17.0 per 1,000 population being 2.3 below that recorded for that quarter and 0.2 below the average of the preceding five years. Of the total births 6.3 per cent. were illegitimate, 0.1 below that for the immediately preceding quarter and 0.3 below the last five years' average for the third quarter of the year.

Deaths.—Deaths numbered 13,804 (11.0 per 1,000 population), or 1,800 fewer than in the previous quarter, while the rate is 1.6 less. The rate is, however, 0.2 above the average for this quarter of the last five years. Deaths of children under 1 year numbered 1,232, equivalent to an infant mortality rate of 5.8 per 1,000 registered live births: the rate is 7 less than in the previous quarter and 2 less than the five-year average for this quarter. The rates for legitimate and illegitimate children were 56 and 81 per 1,000 respectively. The principal epidemic diseases contributed 307, or 2.2 per cent. of all the deaths registered during the quarter: of these, 78 were from diphtheria, 59 from influenza, 58 from whooping-cough, 24 from cerebrospinal fever, and 18 each from scarlet fever and measles. The death rate from this group of diseases is 8 less than the five-year average for this quarter: from measles 3 less, from scarlet fever and whooping-cough 2 less, from diphtheria 1 less, from cerebrospinal fever the same, and from influenza 1 more.

In the United Kingdom and Eire 200,875 births and 128,823 deaths were registered during the quarter, showing an increase of population, owing to excess of births over deaths, of 72,052.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 26, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns (9 in 1937) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.
† Death from puerperal sepsis.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE BRITISH MEDICAL JOURNAL, *Aitology Westcent, London.*

SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Éireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin.)

QUERIES AND ANSWERS

Painful Micturition

"G. P." writes: I should be obliged for information as to dietetic and medicinal treatment in a case in which there is smarting on micturition, especially at night. The patient is aged 71 and has an enlarged prostate and some nasal sepsis. The urine is loaded with uric acid and oxalates.

Case for Diagnosis

Mr. C. A. HUTCHINSON, F.R.C.S.Ed. (Bath), in reply to Dr. E. S. Hawkes (November 19, p. 1070), writes: In addition to the dental investigation suggested by "Nemo" (November 26, p. 1126), I would like to stress the need for thorough investigation of the paranasal sinuses. By this I do not mean the more or less cursory examination by anterior and posterior rhinoscopy, with possibly transillumination, so frequently considered sufficient to give the sinuses a "clean bill of health," but careful rhinoscopy by a rhinologist, and on the discovery of any suspicious signs, suction lavage of the sinuses with bacterial investigation of the sinus washings. The facts that the patient looks ill, has extreme lassitude, and that there is a definite periodicity in the pyrexial attacks suggest the strong possibility of a "latent" chronic sinusitis, which ordinary methods of investigation would fail to reveal; whereas in all probability fuller investigation along the lines suggested above would yield instructive and, I hope, definitely helpful findings.

Condensation Water from Theatre Skylight

Dr. A. A. MASSER (Penistone, near Sheffield) writes: In reply to Dr. E. S. Hemsted's inquiry (December 3, p. 1188) for a remedy against water condensation on windows, I suggest that he apply to the glass daily the "antidimming outfit" as supplied with the Special Service Respirator. This is spread uniformly with a cloth over the glass and will last a whole day, and prevent any dimming by condensation on the windows. The same antidimming substance can be obtained from any opticians.

Dr. CONSTANCE OTTLEY (Hove) also writes: I would suggest that the following contrivance would meet the case: a sheet of glass, slightly larger than the skylight, is fixed (perhaps suspended by chains) a short distance below the skylight and slanted slightly from the horizontal in such a way that any water condensed on the under side of the glass or dropping from the skylight on to its upper side can run off harmlessly and drop on the floor beyond the operating table.

LETTERS, NOTES, ETC.

Medical Register: Office Edition

The Registrar of the General Medical Council informs us that orders for the Office Edition of the *Medical Register*, 1939, published by the Council at the special price of 10s. a copy, post free, must be received, with a remittance, at the office of the Council not later than December 31, 1938. This edition differs from the ordinary edition to the extent that it does not contain reprints of the Medical and Dentists Acts and other preliminary matter, and is printed on more inexpensive paper and bound in boards. It includes, however, the same entries relating to registered medical practitioners as are included in the ordinary edition, and is therefore equally serviceable to public authorities and others who find it necessary to ascertain whether particular persons are registered medical practitioners or not. The Council also prepares monthly lists of names added to, and removed from, the *Register*, and particulars of the terms and conditions upon which copies of these lists may be made available can be obtained on application to the office of the Council, 44, Hallam Street, Portland Place, London, W.1.

A Warning

The Secretary of the Essex Public Medical Service writes: The other evening I had a visitor who introduced himself as "Dr. Wilson of Rochford"; he had no time to stay, in fact a taxi was waiting, but he would like to see me on the following day to talk over several matters. He had to go to St. George's Hospital to be present at operations on two of his patients, and as he would probably have to stay in town over the night, and had come away with little cash, he would be obliged if I would lend him a pound or two. That evening I phoned up Dr. Wilson of Rochford (who had not been out of the place) and St. George's (where he was unknown). I informed the police, and later a detective from Scotland Yard brought a number of photos, one of which I recognized as that of "Dr. Wilson"; the photo had been taken in prison. This man, it appears, is a clever and plausible rogue who has victimized many doctors and medical organizations. He is wanted on many charges in London and in provincial towns. He always poses as Dr. Somebody, is always on the way to an urgent case, and usually has a taxi waiting. He plays his part well. He is 70 years of age; jolly manner; short and thick-set; full, flabby face with reddish complexion; bald, with fringe of whitish hair above the ears.

Quick Sales

Dr. J. S. LOUGHRIDGE (Belfast) writes: It may interest your readers to know how the representatives of a certain well-known encyclopaedia are making "quick" sales. A girl calls and asks if one is willing to receive a copy of their encyclopaedia without obligation: she explains that the publishers are "giving away" a number of copies to a few carefully selected people as an advertisement. The obligation, after acceptance, amounts to £29 10s.

Calendars and Diaries

The 1939 diaries and calendars of Messrs. John Walker and Co. Ltd. (5 and 6, Warwick Lane, E.C.4) are well up to the standard of previous years, both in appearance and in usefulness. The desk diaries, with spaces for the half-hour and quarter-hour appointments, are especially suitable for the busy medical practitioner. Pocket diaries can be obtained with one page (or less) for every day of the year, according to individual requirements. The bindings leave nothing to be desired, being both attractive and serviceable. The prices range from 1s. upwards.

The Dental Manufacturing Co. Ltd. (97, Great Portland Street, W.1) have issued their diary of appointments for 1939, containing space for half-hourly appointments, as well as several pages of information of use to dental practitioners. The separate address book, clipped inside the back cover, should be much appreciated. The price of the plain edition of the appointments book is 6s. 6d. (postage 6d. extra).

Hormone Therapy

We have just received from Organon Laboratories, 77, Newman Street, London, W.1, a booklet describing the standardized biological products prepared by this firm, and entitled *Hormone Therapy*. Copies of these will be sent to practitioners on application.

 Hypertension and Health Diagnosis. W. Emerson and J. Irving.—p. 1174.
 Use of Vitamin D Preparations in Prevention and Treatment of Disease. E. Park.—p. 1179.

Cold Vaccines.—In the University of Minnesota, Diehl, Baker, and Cowan inoculated large groups of students with coryza vaccines. A control group receiving sterile solutions of sodium chloride under the impression that they were coryza vaccines was observed. This group experienced an average of 25 per cent. more colds per person than that inoculated with vaccines. All students were subjected to an oto-laryngological examination. It was found that the condition of the nose and throat was not related to the frequency of colds in the cold-susceptible group. The authors do not believe that the slight reduction of colds after inoculation justifies the time and expense involved, or that vaccines reduce the complications of colds.

Klinische Wochenschrift

 Inducing Light Hypnosis by Hyperventilation. W. Sargant and R. Fraser.—p. 778.

Heart Sounds.—In a summary of the work of various South American investigators graphic methods of recording the heart sounds are described. There are four sounds, of which the third is often audible and the fourth (auricular), although only sometimes audible, can always be recorded in man from the oesophagus. The causation of the sounds in gallop rhythm is discussed, and a phonocardiographic analysis of auriculo-ventricular heart-block is given.

Problem of Sterilization within the Hospital. C. Naeslund.—p. 1535.
History of Art of Embalming. Y. Lewegren.—p. 1539.

Sea-sickness.—Clinical and pharmacological tests of β -phenyl-isopropylamine (benzedrine) have been carried out by Ekerfors in 116 cases, the clinical results being favourable in 87 per cent. A comparison of the action of this drug with that of belladonna preparations proved definitely favourable to the former.

Presse Médicale

Paris vol. 46 September 28, 1938

- *Vitamin B₁ in Treatment of Pain of Nervous Origin. F. Coste and J. Metzger.—p. 1433.
*Trial Treatment of Asthma with L-ascorbic Acid (Vitamin C). D. Hargreaves, Gh. Bazavan, M. Criscuta, and M. Cioranescu.—p. 1435.
Return to Work and Social Prospects of Sufferers from Pulmonary Tuberculosis. A. Fabre.—p. 1438.

Vitamin B₁ and Pain.—Coste and Metzger have been using injections of vitamin B₁ in the treatment of pain. They give a short account of eighteen cases of lumbago, sciatica, cervicobrachial neuralgia, scapulo-humeral periarthritis, arthritis of the hip, post-herpetic neuralgia, etc. Most cases were relieved or cured, at times far more rapidly than could be accounted for by the usual mechanism as seen, for instance, in beriberi or in alcoholic polycuritis.

Vitamin C and Asthma.—The authors give the results of their treatment of twenty cases of asthma; fifteen reacted favourably. As a rule the effect of the treatment was less marked in cases with acute attacks than in cases with prolonged successive daily attacks.

Paris vol. 46 October 1, 1938

- *Foetor Oris. G. Sanarelli.—p. 1449.
*Haemorrhagic Rectitis. P. Outy and R. Stieffel.—p. 1452.

Foetor Oris.—The author, after discussing the various views held on this subject, comes to the conclusion that true foetor oris is of local origin and is due to various forms of putrid fermentation in the buccal cavity.

Haemorrhagic Rectitis.—The authors describe two cases of this disease and stress the importance of differentiating it from haemorrhagic rectocolitis, which is a much more serious condition.

F. Schroder and C. Johansen.—p. 1074.
Treatment of Infections of Urinary Tract with Granulatum Catu Amygdalatis.
K. Rasmussen.—p. 1052.

Urethritis Simplex.—In the course of three months of dispensary practice Genner found among male patients fifty-seven cases of gonorrhoea and fifteen of urethritis simplex. In his private practice he observed ninety-three cases of urethritis simplex to 138 cases of gonorrhoeal urethritis in the same period. He concludes that urethritis simplex is much more common in both sexes than has hitherto been suspected.

—p. 1091.
*Scarlet Fever Control. E. R. Krumbiegel.—p. 1096.

Scarlet Fever Control.—This investigation was undertaken to determine the protective value of the five standard injections of scarlet fever toxin among Dick-positive subjects during a period of exceptionally high incidence of the disease in Milwaukee. Over a three-year interval it was found that the incidence rate was fourteen times higher in non-immunized Dick-positive reactors than among similar subjects who had undergone the full immunizing course. A previous attack of scarlet fever gave better protection than the immunizing course or a Dick-negative reaction. The practical value of re-Dick-testing was considered negligible. A culture filtrate as free as possible from endotoxin is desirable, at least for skin-testing.

Can Infection be presented in Fresh Wounds? W. Ehalt.—p. 1081.
Felly's Syndrome. W. Breu and H. Fleischhaeyer.—p. 1081.

Toxaemias of Pregnancy.—Siegmund divides the toxaemias of pregnancy into three groups: (1) Disturbances in the endocrine-vegetative system; symptoms include hyperemesis, pyalism, waterbrash, and atonic constipation, and occur during the first three months. (2) Disturbances occurring preponderantly in any one organ, which may be skin, liver, biliary tract, haemopoietic or central nervous system; the symptoms become apparent at any time during pregnancy. (3) Symptom-complexes which include oedema of pregnancy, albuminuria, essential hypertension, and eclampsia. They occur commonly in the latter third of pregnancy and appear to be due to the influence of the foetus. Prophylaxis is comparatively easy; pregnant women should be encouraged to eat carbohydrate and vitamin-rich food. Proteins, fats, sodium chloride, and fluids should be restricted.

 *Studies on Oxyuriasis: VII, Clinical Improvement following Treatment with Single Doses of Tetrachlorethylene. W. H. Wright, J. Bozicevich, and L. S. Gordon.—p. 609.

Yellow Fever Vaccination.—Inoculation of 59,000 persons with cultured virus, strain 17D, shows that it is a safe and efficient method of large-scale immunization. Any reaction is mild, consisting of headaches, low-grade fever, and influenzal-like pains, and appears on the sixth or seventh day; no delayed reactions have been encountered. Antibodies appear in the blood between the seventh and twenty-first day after inoculation and persist for at least a year.

Beriberi and Inanition.—Rats starved to death showed degenerative nerve changes which could not be prevented by the administration of vitamin B₁. Rats fed on protein gained weight and had no degeneration of peripheral nerves; those fed on fat also had no nerve degeneration although they suffered from inanition; but those fed on carbohydrate developed degeneration of nerves in spite of vitamin B₁ daily. These facts throw doubt on the theory that the nerve degeneration of polyneuritis is due to pyruvic acid.

Mosquito Studies.—Anopheline larvae were stained in various ways; Giemsa, Wright, methylene-blue, and Congo-red stains were relatively non-toxic and could be recognized in the adult mosquitos several weeks after emergence.

Oxyuriasis.—A single dose of tetrachlorethylene produced a favourable clinical result; three weeks after treatment anal swabs were negative in 47 per cent. of treated cases.

Annales d'Hygiène Publique, Industrielle et Sociale

Paris New Series No 10 October, 1938

- *Commercial Combustion of Household Refuse in Modern Incinerators. L. Hugoueney.—p. 429.

- Organization of Campaign against Paludism in Chile (Regions of Arica-Iquique and Antofagasta). Monnier.—p. 443.
 Dryeries for Sheep Pelts. P. Bellon.—p. 446.
 Report of First International Congress of Cosmobiology (Nice, June 2-7, 1938).—p. 456.

Incineration of Refuse.—The commoner methods of disposal of household and other refuse are reviewed, to the advantage of incineration in modern, specially constructed plant. Analyses of the material content of refuse for certain French towns are given, as also the basic elements in dry refuse, the incinerated ash, and the flue gases. On the hygienic side the absence of nuisance to the public and the protection afforded to employees by automatic handling of the material are commented upon, while on the commercial side the production of electricity and utilization of the ash for manufacture of paving is shown to be a substantial set-off to overhead charges and cost of running.

Annales de Médecine

Paris vol. 44 October, 1938

- Septicaemia and Pyaemia caused by *B. funduliformis*. A. Lamierre, J. Reilly, and A. Laporte.—p. 165.

Pathogenic Bacteria in Air.—Pathogenic bacteria are universally present in the air of operating theatres. The degree of contamination is directly proportionate to the number of occupants. Staphylococci are present in the upper respiratory tract of a large proportion of the population and, in the author's opinion, wound infection by organisms of this type, as in the case of other pathogenic bacteria, arises more frequently from sedimentation from the air than from faulty handling of the skin. The importance of exclusion of staphylococcus carriers and of shielding sterile supplies from sedimentation from the air is emphasized.

Dead Fascial Grafts.—This is an experimental study showing that in animals heterogeneous grafts preserved in 70 per cent. alcohol are well tolerated and gradually replaced, a local fibroblastic reaction leading to reconstitution of the tendon defect so treated.

Contribution to Clinical Functional Tests of Respiration and Circulation. H. W. Knipping.—p. 144.
*Morphology and Origin of Intraclavicular Tuberculous Round Infiltrations. E. Uehlinger.—p. 170.

Intraclavicular Tuberculous Round Infiltrations.—Small, round, sharply defined shadows are often seen in lung fields apparently devoid of other lesions, and a tuberculous origin has been attributed to them. Uehlinger reports in detail a case with full post-mortem (including histological) findings, and reviews the whole subject. He refers to the round infiltrations as pre-phthisical infiltrations, describes their varying histological appearances, and discusses their fate. It is rare for complete resorption to occur, but they may remain unaltered in size for many years or they may gradually enlarge, or cavitate spontaneously following a non-tuberculous inflammation in the neighbourhood. The latter event would explain the development of phthisis as a sequel to non-tuberculous pulmonary illnesses.

- Case of Calcification in Epicondylar Bursa at Elbow. A. R. Hamilton.—p. 446.
- *Surgical Treatment of Obstructive Jaundice in Pancreatic Disease. J. Fraser.—p. 393.

Bladder Mucosa and Stone Formation.—In rats on a vitamin-A-deficient diet marked hyperplasia with active mitosis of the bladder epithelium was followed by metaplasia to the squamous type. Urinary calculi formed frequently in the bladder. Somewhat similar changes have been noted in biopsy specimens removed from the bladders of Chinese patients suffering from vesical calculus, but only one of eleven cases showed clinical signs of vitamin A deficiency.

Saccular Aneurysms of Internal Carotid.—This is a comprehensive study based upon a large number of cases. Clinically it is shown that three distinct syndromes may be recognized characteristic of the posterior, middle, and anterior cavernous regions, differing from each other in the degree of involvement of the trigeminal and oculomotor nerves. The radiographic changes of enlargement of the superior orbital fissure, parasellar calcification, and enlargement of the carotid canal are well illustrated.

Aspiration Biopsy.—An accuracy of 60 per cent. obtained by this method of examining smears of material aspirated from superficial lesions compares well with the results of surgical biopsy.

Gastro-oesophageal Junction.—Dissection shows that in man the sympathetic supply to the cardia comes, in part directly, from the lateral sympathetic chains from the sixth to the tenth segments and from the splanchnic nerves, in addition to fibres accompanying the inferior phrenic and left gastric arteries and fibres coming from the hepatic plexus. Left gastric sympathectomy, therefore, only produces a partial denervation of the human cardia. The possibilities of more extensive procedures in the treatment of cardiospasm are discussed.

Extradural Haemorrhage.—A review of twenty cases, illustrating the possible sites of clot formation, including the syndrome of extradural haemorrhage in the posterior fossa. The possibility of operation for the relief of acute cerebellar compression is discussed.

Obstructive Jaundice in Pancreatic Disease.—The results of an analysis of 1,035 cases—as reported to the Association of Surgeons. Early operation is advocated on account of the difficulty of precise diagnosis between chronic pancreatitis and malignant disease, and the advantage gained in operating before hepatic and renal function are seriously impaired.

1244 F

Immunization of Nurses.—At the St. John General Hospital (New Brunswick) immunization of nurses against scarlet fever has been practised since 1924. In the preceding five-year period, of 224 nurses in training eleven contracted scarlet fever (5 per cent.). From 1925 to 1937, out of 1,132 nurses there were only five cases (0.4 per cent.). The authors conclude that toxin immunization is of definite value and is unattended by disability.

Blood Groups in Poliomyelitis.—Previous investigations on small numbers of patients suggested that there was a relationship between the blood group and resistance to poliomyelitis infection. Working with a series of 703 patients and 1,000 controls, the authors confirm the findings of Madsen, Engle, and Jensen (Denmark) that susceptibility bears no relation to the blood group of the patient.

Current Researches in Anaesthesia and Analgesia

Elmhurst, N.Y. vol. 17 September-October, 1938

- *Use of Inert Gases in Anaesthesia Atmospheres: Relationship to Problem of Post-operative Pulmonary Complications. G. E. Burford.—p. 241.

- *Studies on Pharmacological Properties of Trichlorethanol. H. Molitor and H. Robinson.—p. 258.
- *Use of Helium in Anaesthesia. U. H. Eversole.—p. 264.
- Department of Anaesthesia, Hartford Hospital: Report for 1937. R. M. Tovell.—p. 268.
- Proposed Method for Evaluating Safety of Anaesthetics. A. H. Kibler.—p. 272.
- Evipan in Dental Surgery. O. P. Clark.—p. 286.
- Some Observations on Anaesthesia Abroad. W. L. Garth.—p. 292.
- Two Unusual Complications in Patients under Cyclopropane Anaesthesia. H. R. Griffiths.—p. 298.

Inert Gases and Post-operative Pulmonary Complications.—Burford discusses the pathology of atelectasis, and reviews the recent work upon this subject. He puts forward the theory that the condition is due to lack of inert gases in the respired atmosphere—for example, nitrogen, helium, or hydrogen.

Trichlorethanol.—The action of trichlorethanol has been studied experimentally, and compared with that of tribromethanol, alone and in solution in amylene hydrate. Trichlorethanol has been shown to be slightly less toxic and to have a greater hypnotic effect than tribromethanol; apart from the fact that it occasionally causes extrasystoles, its effects are in general very similar to those of tribromethanol.

Helium in Anaesthesia.—Eversole gives an account of the history, properties, and clinical use of helium. Its value in anaesthesia depends on its low specific gravity and rapid rate of diffusion, which render it useful in the relief of various types of respiratory obstruction.

Journal of Hygiene

- *Experiments on Staphylococcus Food Poisoning. F. C. Minett.—p. 623.
- Adsorbent Effects of Various Dusts on Diluted "Old Tuberculin". S. L. Cummins and E. M. Williams.—p. 638.

Staphylococcal Food Poisoning.—The feeding of culture filtrates to monkeys, dogs, or cats was found unsatisfactory as a test for the presence of staphylococcus enterotoxin, but intraperitoneal injection in kittens, as recommended by Dolman,

gave consistent results. This test served to demonstrate the formation of enterotoxin by sixteen out of thirty-eight strains of *Staphylococcus aureus* obtained from cases of mastitis in cows or from normal cow's milk; some strains of *Bact. coli* from calves with enteritis also formed it, but mastitis streptococci did not. The formation of the toxin during storage was demonstrated in both milk and cream layer cake infected with *Staphylococcus aureus*. The properties of the toxin are described.

Critical Review: Technique and Application of Electro-encephalography. W. Grey Walter.—p. 359.

Morphology of Neurone.—In this paper the author describes in detail the normal nerve cell and fibre, and the effects on it of such processes as ischaemia, cerebral oedema, avitaminosis, and infection with neurotropic viruses. The axonal reaction and transneuronal degeneration are also discussed.

Case of Aphasia.—The patient, aged 56, had aphasic disturbances, characterized by a striking impairment of ability to name objects and of his capacity for reflection, following a left middle cerebral thrombosis. There was also a marked change in personality with loss of the capacity for abstract conception. The anatomical findings are described and the clinical picture is discussed in relation to these findings.

Simple Medium for Cultivation of Tubercle Bacillus. S. R. Jamieson.—p. 353.

Influenza Bacillus Endocarditis.—Two cases of endocarditis are recorded which were due to *Haemophilus para-influenzae*, and the characters of these and other strains are fully described. A survey of the literature of "influenza bacillus endocarditis" suggests that the condition is usually due to this organism; in no case when *H. influenzae* itself was alleged to have been found has its identity been proved by demonstrating its dependence in culture on the presence of both X and V factors.

Streptococcal Allergy in Rheumatism.—A series of skin sensitivity tests in acute and subacute rheumatism with a variety of

streptococcal products showed that the endotoxin of *Streptococcus pyogenes* is the only reagent to which these patients react more often (75 per cent. positive) than do non-rheumatic controls (24 per cent. positive). Attempted desensitization by injections of this material sometimes caused reactions resembling transient relapses of the disease.

Male Sex Hormone. J. Eidelstein.—p. 1537.

Mentegracht Treatment of Bleeding Peptic Ulcer.—The treatment is essentially a programme of liberal feeding immediately upon the hospitalization of a patient for haematemesis and melaena from ulcer. The diet is supplemented by the administration of iron compounds (ferrosi lactatis) and a mixture (sod. bicarb., mag. subcarb., extr. hyoscyam.) designed to exert an antacid and antispasmodic effect. Thirty cases treated in this way were compared with thirty cases treated by the Lenhartz method. In one patient haemorrhage

recurred three months after discharge, but recovery was prompt under the new treatment. No deaths were recorded, as compared with six deaths among the Lenhartz group. Of those surviving, one had a recurrence of the haemorrhage and another developed perforation and required immediate surgical intervention. In Meulengracht's own report the mortality rate from haemorrhage was reduced from 8.1 per cent. to 1.3 per cent. in a series of 368 consecutive cases.

Primary Bronchogenic Staphylococcal Pneumonia.—Primary staphylococcal pneumonia in children is more frequent than the secondary form. The incidence is increasing, and it occurs more often in very young infants. These children quickly develop empyema or pyopneumothorax. Continued aspiration or the closed drainage operation is advisable. Toxoid therapy and vaccine treatment have some prophylactic value; treatment with antitoxin may be effective in uncomplicated cases. Certain strains of staphylococci are more toxic than others; their colonies have a bright yellow colour and are haemolytic.

- Distribution of Quinine in India. A. J. H. Russell.—p. 1566.

Cholera Prophylaxis in Philippines.—Ships from cholera-infected ports are constantly calling at the Philippine Islands (Port of Manila), and consequently special preventive measures must be adopted. These measures comprise anti-cholera vaccination before embarkation at an infected port, modified quarantine on arrival so as not to cause undue delay of voyage, and immediate bacteriological examination of the evacuations of suspected persons irrespective of travelling class. Pending results of examination, passengers may remain on board or may be accommodated at the quarantine station. The delay seldom exceeds the period of normal sojourn of the ship in port. Positive cases are removed to hospital. Each ship and each passenger is dealt with according to the merits of the case, and every consideration shown so far as is compatible with safety. The published figures indicate that the measures adopted are attended by remarkable success.

Swollen Atrophic Hand.—A review is given of fourteen cases in which a peculiar swelling, accompanying atrophy of the skin, interosseous muscles, and sometimes of the bones of one hand, was found to be correlated with unilateral bony constriction of intervertebral foramina in the upper cervical spine on the side of the affected hand. The article is fully illustrated and the method of treatment described, together with the results obtained in seven cases.

Blood Changes in Necrosis of Heart and of Striped Muscle.—In twenty-five patients with myocardial infarction a higher blood sedimentation rate and an increase in blood sugar content, non-protein nitrogen, and leucocytes were observed. The same results were obtained in dogs with small, sterile, artificial muscular necroses of the thigh. It is assumed that in both instances the changes are due to the resorption of necrotic products.

Peridural Anaesthesia.—According to the author this is the ideal method of anaesthesia for the great majority of urological operations. Many advantages over spinal (intradural) anaesthesia are claimed, and in 1,000 operations under peridural anaesthesia there were no fatalities attributable to the anaesthetic. A fall of blood pressure with collapse of a grave nature did occur in eleven cases, but all responded to the injection of coramine and similar drugs. The anaesthesia lasts for two and a half to three hours. The technique is said to be simple.

HORMONE TREATMENT

in
imperfect
descent
of the
testis

"The disadvantage of waiting for spontaneous descent in any except the retractile type is that if an anatomical abnormality be present, the diagnosis of which may deceive even the elect, spontaneous descent can never occur. Waiting until after puberty in the hope of spontaneous descent is in such a case an unnecessary and unjustifiable delay. Analysis of the results in the present series shows that if in cases of doubt a retained testis does not respond after six months of hormone treatment, it is highly probable that there is an anatomical abnormality."

Support without Constriction with the LINIA BELT

designed under medical supervision to correct PTOSIS, OBESITY, FAULTY POSTURE, INTESTINAL STASIS and ENTEROPTOSIS. Invaluable, too, for POST-OPERATION WEAR.

THE Linia Belt has been scientifically designed, with the help of eminent medical men, to support the abdomen with an uplifting action, by means of a system of slide buckles acting on panels of elastic tricot—as described below. It avoids the danger of exercising direct restricting pressure on the abdomen.

Arrow No. 1.—Shows how the Linia Belt acts on parts that are usually protuberant, in harmony with the over-all pressure.

Arrow No. 2.—Shows how the Linia Belt lifts and holds in place the lower abdominal parts that have sagged and dilated.

Arrow No. 3.—Shows uplifting support on the groin, a protection against rupture and strain.

Besides affording support and restoring displaced organs to their correct position, the Linia Belt exerts a gentle massaging action, dispersing adipose tissue, and bracing and toning the muscles. It is invaluable, too, for post-operation wear, and to prevent strain when older men, unused to violent physical effort, take exercise.

FRONT VIEW. At the front of the belt the thin non-elastic porous tricot of great strength is extended to the required depth, so that a gentle pressure is exerted on the full area of the abdomen.

BACK VIEW. The tough, like, horizontal elasticity of this special tricot can be regulated to the required tension with slide buckles. Thus its lifting and massaging powers are easily controlled.

We shall be pleased to forward a specimen Linia Belt for your examination on approval.

YOU CAN ORDER BY POST. Money refunded at once if dissatisfied. PRICES: Linia Belt, including a Linia Jock Strap: Popular Model, 3½ gns. (Black, 4 gns.). De Luxe Model in pure silk, extra light quality, 6 gns. (Black, 7 gns.). Standard Model, 2 gns. C.O.D. 1/- extra.

We make a reduction of 2/- in the £ on purchases for personal use to members of the Medical Profession. May we send you a fully explanatory booklet?

IMPROVED MAW STEROTHERM

HOT AIR ELECTRIC AUTOMATIC STERILIZER

(Patent No. 427581)

A thermostatically-controlled electrical apparatus for sterilizing Oils, Instruments, Glassware, Syringes, Dressings, and I.R. Gloves, etc., by means of Hot Air. Specially suitable for Hospitals, Nursing Homes, Doctors, Dentists, Veterinary Surgeons and Laboratory work.

- Compact Reliable and Convenient (2 sizes).
- High quality White Cellulose finish.
- Efficiently lagged.
- Polished Aluminium Heat Reflecting Lining.
- Easily read Thermometer.
- Automatic regulation of temperature.
- No supervision necessary in use.
- Very small current consumption.
- Articles remain sterile until required as closure is Bacteria-proof.
- Can be plugged in anywhere the voltage is suitable.
- Supplied in any voltage, complete with fittings.

A New B.M.A. Specialist Publication

BRITISH HEART JOURNAL

The first issue of this new quarterly Journal, jointly edited by Dr. Maurice Campbell and Dr. Evan Bedford, assisted by an Editorial Board appointed by the Cardiac Society, will be published in January, 1939. The new periodical will include matter dealing with everyday diagnosis and treatment of patients and will, therefore, be of value to the general practitioner as well as to the cardiologist to whom it will have an obvious appeal.

An announcement of the contents of the forthcoming number will appear in due course.

ISSUED BY THE BRITISH MEDICAL ASSOCIATION

In acting as an executor or trustee, the Westminster Bank aims at putting itself in the position of a private trustee. It is therefore its practice to employ the family solicitor, if there is one, or any other solicitor the client may name; by such means the Bank succeeds in combining domestic tradition with business efficiency. A book showing the advantages of corporate executorship and the terms of appointment may be had at any branch or at the branch situated in B.M.A. House, Tavistock Square, W.C.1

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D., M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 350 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park. At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

CRICHTON ROYAL, DUMFRIES
NERVOUS AND MENTAL DISORDERS

Cases of alcoholism and drug addiction are admitted.

This Hospital has every facility for complete investigation and treatment of the above conditions.

The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy. There is a fully equipped Gymnasium and indoor Swimming Bath under qualified instructors. Facilities are provided for all indoor and outdoor recreation, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens, and a Cinema.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country, and include an extensive farm (T.T. herd), gardens and orchards.

Private rooms, suites or villas are available, and special nurses can be provided.

As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week; Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Supt.: P. K. MCCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law. Tel.: Dumfries 1119

BOWDEN HOUSE,

HARROW-ON-THE-HILL.

For the residential treatment of Functional Nervous Disorders

No case under certificate nor under the M.T.A.

This home, which was founded in 1911, is designed to provide for psychoneurotics a curative environment associated with modern psychological treatment modified to suit each individual patient. The treatment is in the hands of three experienced psychotherapists, and most patients receive three hours of analytical treatment per week. Occupational-therapy of many varieties is available but not obligatory. Recreations include tennis, badminton, billiards, etc.

On admission patients are examined by the diagnostic physician, who advises on all physical treatment. As far as possible all necessary pathological examinations are carried out by the pathologist in the laboratory on the premises.

STAFF:

H. CRICHTON-MILLER, M.A., M.D., M.R.C.P. (Senior Physician). GRACE H. NICOLLE, M.A., M.B. (Resident Physician).
ALFRED TORRII, M.A., M.B., Ch.B., D.P.M. (Medical Superintendent). MARY HALL, M.B., B.Ch. (Pathologist).

POST-GRADUATE COURSE IN VENEREAL DISEASES

LONDON COUNTY COUNCIL (WHITECHAPEL)
CLINIC, TURNER STREET, E.1
(ADJOINING THE LONDON HOSPITAL).

A THREE MONTHS' COURSE OF INSTRUCTION IN MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES will be given by Lieut.-Colonel E. T. BURKE, D.S.O., the Director of the Clinic, during January, February and March, 1939. Attendance at this Course will qualify, subject to the other conditions in the Regulations of the Ministry of Health, for the Certificate enabling the possessor to hold the position of a Venereal Diseases Officer under the Council of a County or County Borough. The Course will consist of twenty-five systematic lectures, accompanied by lantern demonstrations, on Mondays and Thursdays at 2.30 p.m., beginning on 9th January and ending on 30th March, 1939. Every Wednesday at 2 p.m. cases will be demonstrated. Those taking the Course will also attend the practice of the Clinic in order to obtain tuition in intravenous injections, etc. During the three months 130 hours of attendance must be put in.

Those intending to take the Course must send their names to the Director on or before 20th December, 1938. Fee: £10 10s.

UNIVERSITY OF LEEDS. FACULTY OF MEDICINE.

The Council will shortly proceed to the appointment of a SECOND SURGICAL TUTOR, at a salary of £400 a year.

Further particulars may be obtained from the Registrar, The University, Leeds, 2, who will receive applications for the post on or before December 23rd.

SOUTHPORT GENERAL INFIRMARY. (150 Beds.)

Special Departments for Eye, Ear, Nose and Throat. X Rays, Massage, Skin, Pathology, etc.

Wanted to take up duties on January 1st next, a SENIOR HOUSE SURGEON. Salary £250 per annum, with residence, board and laundry. Applicants to be fully qualified, registered and unmarried.

One Junior House Surgeon and one Junior House Physician also on the Staff.

Applications, stating age and experience, with copies of testimonials, to be sent in by December 19th, 1938, to the Superintendent and Secretary, Infirmary Office, Pilkington Road, Southport.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry at the end of March, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list. Marriage Allowance is paid under the same conditions as for other Naval Officers.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1939.

ROYAL NAVAL DENTAL SERVICE

Applications are invited for appointment to commissions as DENTAL OFFICERS in the ROYAL NAVY.

Candidates, who must be British subjects below the age of 28 years, must hold the degree of diploma of a British University or College of Surgeons, and be registered under the Dentists Act or Medical Act. Unmarried candidates are preferred. No examination in professional subjects will be held, but candidates will be required to attend at the Admiralty for interview, and for physical examination as to their fitness for service in any part of the world.

Successful candidates will be appointed to short service commissions as Surgeon Lieutenants (D) and will receive a grant of £50 towards the cost of providing the necessary uniform on entry. Vacancies in the permanent list will be filled by selection from among officers holding short service commissions who desire to make the Royal Naval Dental Service their permanent career. Officers not transferred to the permanent list will, on the termination of their short service engagement after six years' service, be eligible for a gratuity of £1,000.

Opportunities are available for officers on the permanent list to obtain post-graduate study. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances. Naval Dental Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Application forms and copies of the regulations for entry and conditions of service, rates of pay and allowances, etc., may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of Dental Schools.

ROYAL VICTORIA INFIRMARY, Newcastle-upon-Tyne. (R35 Bedd.)

MEDICAL REGISTRAR—Open Appointment.

Applications are invited for the post of Medical Registrar, to take up duty on February 1st, 1939. Candidates must be registered in Medicine and in Surgery. The salary is at the rate of £250 per annum (non-resident).

Further particulars regarding duties, times of attendance, etc., may be obtained from the undersigned, to whom applications, with copies of not more than three testimonials, should be sent not later than December 31st, 1938.

S. DUNSTAN,

House Governor and Secretary
December 5th, 1938.

SOUTHERN RHODESIAN GOVERNMENT SERVICE

VACANCY FOR PATHOLOGIST

Required by the Government of Southern Rhodesia a PATHOLOGIST for appointment as Director of a Public Health Laboratory in Southern Rhodesia.

Applicants should be experienced in all branches of laboratory work, including Bacteriology, Biochemistry, Haematology, Protozoology, etc.

Salary will be at the rate of £1,000 per annum, rising by annual increments of £50 per annum to £1,250 per annum.

The appointment will be on contract for the first year, for a probationary period of two or three years, thereafter the incumbent will be considered for appointment to the pensionable staff and particulars regarding pension and leave may be obtained from the Official Secretary, Office of the High Commissioner in London.

The successful applicant will be required to assume duty at the Public Health Laboratory, Bulawayo, Southern Rhodesia, as soon as possible and by steamship passage from England to Cape Town and railway fare from Cape Town to Bulawayo will be paid by the Government.

Applications, accompanied by testimonials, references, etc., and full information as to when services will be available, if appointed, should reach the Official Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429, Strand, London, W.C.2 on or before December 16th, 1938.

COUNTY MENTAL HOSPITAL, Prestwich, near Manchester

Applications are invited for the whole-time appointment of SENIOR ASSISTANT MEDICAL OFFICER at the above Mental Hospital. The salary is £700 per annum, an additional £50 per annum will be paid for the possession of a Diploma in Psychological Medicine.

The selected candidate must be single, and will be required to live in the Hospital and will be provided with board, lodgings, etc., for which a charge of £150 per annum is made.

The appointment will be subject to the provisions of the Asylums Officers' Superannuation Act, and the successful candidate will be required to pass a medical examination.

Applications, giving full particulars, with copies of testimonials, should be forwarded to us to reach the Medical Superintendent on or before January 4th, 1939, address as above.

SURREY COUNTY COUNCIL

PUBLIC HEALTH DEPARTMENT

FARNHAM COUNTY HOSPITAL (19' Bedd.)

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of Assistant Medical Officer at the Farnham County Hospital, Hale Road, Farnham.

Candidates must have held resident hospital appointments and should preferably possess a higher qualification.

The tenure of the appointment is limited to a period of five years, but the appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. The cash salary is at the rate of £350 per annum, rising by annual increments of £25 to a maximum of £450 per annum, together with full residential emoluments valued at £125 per annum.

Applications, stating age, qualifications and experience, and enclosing copies of not more than three recent testimonials, should be addressed to the County Medical Officer, County Hall, Kingston-on-Thames, so as to be received not later than December 21st, 1938.

County Hall, Kingston-on-Thames, Clerk of the Council.
December 9th, 1938.

BOROUGH OF ILFORD.

APPOINTMENT OF TEMPORARY ASSISTANT MEDICAL OFFICER OF HEALTH (PART TIME) FOR AIR RAID PRECAUTIONS.

Applications are invited from registered medical practitioners—preferably from Medical Officers retired from the Services—for the above position, which will be for a period of six months, which may be extended. The salary will be at the rate of £300 per annum.

The duties of the appointment will be part time under the direction of the Medical Officer of Health, and they will consist mainly in training volunteer personnel in First Aid and in assisting with the administration of the Casualty Services Section of the Borough A.R.P. Scheme. In addition the person appointed will be expected to assume the functions of a First Aid Commandant under the control of the Medical Officer of Health and to examine volunteer recruits for A.R.P. work.

Applications, stating age, qualifications and experience, should be forwarded to the undersigned not later than Saturday, December 17th, 1938.

CHARLES N. ROBERTS,
Town Clerk.

CITY OF STOKE-ON-TRENT EDUCATION COMMITTEE.

SENIOR SCHOOL DENTAL OFFICER.

The Stoke-on-Trent Education Committee invite applications from fully qualified and registered male dental surgeons for the post of Senior School Dental Officer.

Salary will be at the rate of £600 per annum, rising by annual increments of £25 to £700 per annum.

The successful candidate will be required to devote the whole of his time to the duties of the office and work under the direction of the Senior Medical Officer. The duties will consist of supervision of the Authority's Dental Officers, school dental inspection and treatment, the dental treatment of Maternity and Child Welfare Centre patients, and patients of the County Borough Institutions, as required. He must be prepared to undertake clinical work in addition to his supervisory duties.

Previous experience in school dental work for at least three years is essential. Canvassing will be considered a disqualification.

Forms of application may be obtained from the undersigned on receipt of a stamped, addressed foolscap envelope, and completed forms should be submitted not later than January 5th, 1939.

The appointment will date from May 1st, 1939, and will be subject to the Local Government Superannuation Act, 1937.

J. I. CARR.

Director of Education.

Education Offices

Town Hall,

Hanley, Stoke-on-Trent

November 30th, 1938

STAFFORDSHIRE COUNTY COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND MEDICAL OFFICER OF HEALTH.

Applications are invited for the joint whole-time appointment of an Assistant County Medical Officer of Health for the Administrative County of Stafford, and Medical Officer of Health for the Stone Urban (population 6,376) and Rural (population 12,180) Districts. The salary will be at the rate of £800 per annum, subject to a deduction of 5 per cent. established under the Local Government and Other Officers' Superannuation Act, 1922.

Applicants must be fully qualified medical men with experience in public health duties and must hold the Diploma of Public Health. The person appointed will, as regards his duties as Assistant County Medical Officer of Health, act under the direction of the County Medical Officer of Health, and will be required to perform such duties as may be from time to time prescribed. As regards his duties as District Medical Officer of Health, the officer will be subject to the sole control and direction of the local Sanitary Authorities.

The joint appointment is subject to the approval of the Minister of Health and the Board of Education, and also, so far as the office of District Medical Officer of Health is concerned, to the provisions of the Sanitary Officers' (Outside London) Regulations, 1935.

The joint appointment will be subject to three calendar months' notice on either side, subject, so far as the office of District Medical Officer of Health is concerned, to the consent of the Ministry of Health.

The successful candidate will be required to undergo a medical examination and to produce a birth certificate.

Forms of application may be obtained from the undersigned, and should be returned by first post on December 15th, 1938, together with copies of not more than three testimonials.

H. I. UNDERWOOD,

Clerk of the County Council

County Buildings,

Stafford

December 5th, 1938

KENT COUNTY COUNCIL.

SENIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Senior Resident Assistant Medical Officer at the County Hospital, Chatham (D40 bed).

The salary for the appointment is £350 a year, rising by £25 a year to £450 a year, together with residential emoluments, which are valued at £120 a year.

Applicants must have had obstetric experience. Forms of application can be obtained from the P. M. A. Office, Tonbridge Road, Maidstone, to whom applications must be sent by 10 a.m. on Tuesday, December 20th, 1938.

W. I. PLATTS,

Medical Officer, County Council

December 12, 1938

DENBIGHSHIRE COUNTY COUNCIL.

ADDITIONAL ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL INSPECTOR.

Applications are invited from duly qualified medical practitioners under the age of 40 for the appointment of an Assistant County Medical Officer of Health and Assistant School Medical Inspector at a salary of £500 per annum, rising by annual increments of £25 to £700 per annum. Travelling and subsistence allowance will be paid in accordance with the Council's scale.

Applicants must have had at least three years' experience in the practice of their profession subsequent in qualification, and should also have had special experience in the Medical Inspection of School Children, and in Maternity and Child Welfare Work.

As the successful applicant may later be required to take charge of a County District under the County Scheme for Full-time Medical Officers, the possession of a Diploma in Public Health or its equivalent is essential.

The appointment will be a designated post for the purpose of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

A knowledge of Welsh is desirable.

Forms of application and further information may be obtained from the County Medical Officer, County Health Offices, 16, Grosvenor Road, Wrexham.

Applications, accompanied by copies of not more than three recent testimonials, must reach the undersigned not later than first post on Wednesday, December 28th, 1938.

County Offices,

Ruthin.

December 5th, 1938.

WILLIAM JONES,

Clerk to the County Council.

BOARD OF CONTROL.

ENGLAND AND WALES.

The Board of Control (Lunacy and Mental Deficiency) invite applications from registered medical practitioners (men and women) for a vacant appointment as COMMISSIONER on the BOARD'S STAFF.

Candidates should be experienced in the care and treatment of persons suffering from mental disorder or mental defect.

The salary commences at £850 per annum, and rises by eleven annual increments of £30 to £1,180 and then to £1,200 per annum. In the case of a candidate with special experience of the administration of mental institutions the commencing salary may be advanced to a point, not exceeding £75, above the minimum of the scale.

The appointment will be subject to the usual Civil Service conditions as to pension, holidays, etc., and also, in the case of women, marriage. Subject to certain conditions, previous established service in a Mental Hospital or Mental Deficiency Institution can be aggregated with Civil Service for superannuation purposes.

Commissioners are required to devote their whole time to the Public Service.

Canvassing through Members of Parliament or in other ways will render a candidate liable to disqualification.

Forms of application, with further particulars of the appointment, may be obtained from the Secretary, Board of Control, Hobart House, Grosvenor Place, London, S.W.1.

No application can be considered unless received on the prescribed form not later than January 7th, 1939.

BOROUGH OF BERNONDSSEY.

Applications are invited from fully qualified and registered Medical Practitioners (Women—Widows or Single) for the position of ASSISTANT MEDICAL OFFICER for Maternity and Child Welfare.

The salary will be at the rate of £600 per annum, rising by two annual increments of £50 to £700 per annum, and be subject to deductions under the Council's Superannuation Acts. The person appointed will be required to pass satisfactorily a medical examination. Candidates must not have reached their 35th birthday on the date of their application. Preference will be given to applicants having special experience in the care of women and children. The person appointed will be required as a routine duty to give lectures on hygiene to audiences both of school children and of adults, and to devote the whole of her time to the work of the Council. Further particulars of the duties can be had on application to the Medical Officer of Health.

Applications on forms to be obtained from the undersigned and accompanied by copies of not more than three recent testimonials, must be delivered not later than December 19th, 1938.

FRANCIS J. R. MOUNTAIN,

Medical Officer, Spa Road, Town Clerk,

Bernonsey, S.E.16

December 2nd, 1938

LONDON COUNTY COUNCIL.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be sent to the undersigned by December 15th, 1938.

T. L. W. MACKLOW,

Superintendent and Secretary

BOROUGH OF LALING

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified medical men (male) with a Public Health qualification for the position of Assistant Medical Officer.

A candidate must have had at least three years' experience in the treatment of cases of infectious disease at an Isolation Hospital. The duties will include the medical care of patients in the Laling and Breiford and Church Isolation Hospital, South Laling, and the medical inspection and treatment of school children at schools and health centres in the Borough of Laling.

The person appointed will reside at the Isolation Hospital, where he must reside and be paid for his board and lodging.

He will be required to devote his whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £150 per annum, rising by £25 per annum to a maximum of £200, plus board and residence, as indicated above and valued at £150 per annum.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in conformity therewith. Candidates will be a disqualification.

Copies of the application forms and terms of appointment can be obtained from Dr. THOMAS O'D. Medical Officer of Health, Town Hall, Laling, W.S., to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than December 15th.

Town Hall, R. H. WANKLYN, Town Clerk, Laling, W.S.

BOROUGH OF LALING

ASSISTANT MEDICAL OFFICER OF HEALTH

Applications are invited from duly qualified medical men with a Public Health qualification for the position of Assistant Medical Officer of Health.

A candidate must have had at least three years' experience in the practice of his profession. The person appointed will be required to carry out medical inspection of school children and child welfare work and perform such other duties as may be allotted by the Medical Officer of Health and School Medical Officer.

He will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. The salary will be at the rate of £100 per annum, rising by £25 per annum to £175.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in conformity therewith. Candidates will be a disqualification.

Copies of the application forms and terms of appointment can be obtained from Dr. THOMAS O'D. Medical Officer of Health, Town Hall, Laling, W.S., to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than December 15th.

Town Hall, R. H. WANKLYN, Town Clerk, Laling, W.S.

BOROUGH OF HESTON AND ISLWORTH.

Appointment of ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified medical men with a Public Health qualification for the position of Assistant Medical Officer of Health and School Medical Officer.

Candidates will be required to carry out medical inspection of school children, bacteriological work, child welfare work, administer dental anaesthetics, and perform such other duties as may be allotted by the Medical Officer of Health.

The person appointed will be required to devote his whole time to the duties, to reside in the Borough, and will not be allowed to engage in private practice. The salary will be at the rate of £100 per annum, rising to £700 per annum by annual increments of £25.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

Copies of the application form and terms of appointment can be obtained from the Medical Officer of Health, 92, Bath Road, Hounslow.

Applications, accompanied by copies of not more than three recent testimonials, enclosed in a sealed envelope endorsed "Assistant Medical Officer," must be delivered to the undersigned not later than noon on Friday, December 16th 1938.

Council House, HOUNSLOW, HAROLD SWANN, Town Clerk.

CITY OF BIRMINGHAM

PUBLIC ASSISTANCE COMMITTEE

BIRMINGHAM INFIRMARY

ASSISTANT RESIDENT MEDICAL OFFICER

The Public Assistance Committee invite applications from fully qualified medical practitioners for appointment as Assistant Resident Medical Officer at Birmingham Infirmary.

The Institution has accommodation for upwards of 1,000 patients, an increasing proportion of which is in need of chronic sick cases both male and female.

The Officer appointed will be required to assist in the general medical work of the Institution under the supervision of the Resident Medical Officer.

Any further particulars of the Institution and conditions can be obtained upon application to the Medical Officer of Health, Birmingham, M.D.

Salary will be at the rate of £150 per annum, rising to £200 per annum by annual increments of £25 per annum to £450 per annum, together with full residential emoluments (travelling, apartments, laundry and attendance). Four weeks' leave of absence will be granted to the successful candidate.

The appointment will be subject to the candidate satisfactorily passing a medical examination, to be held at one month's notice to terminate on either side. The salary will be subject to deductions in respect of superannuation and (subject to the necessary qualifications) in respect of the Municipal Officers' Widows' and Orphans' Pensions Scheme.

Applications, accompanied by copies of three recent testimonials, should be addressed to the Public Assistance Officer, 102, Edmond Street, Birmingham 1, and forwarded so as to reach him on or before 10 a.m. on Monday, December 19th next. Candidates in any form oral or in writing, direct or indirect, will be regarded as a disqualification.

Council House, H. C. WILSHIRE, Town Clerk, Birmingham, 1, December 2nd 1938.

BOROUGH OF WIMBLEDON

DEPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER

Applications are invited for the above appointment from qualified and registered medical practitioners under 35 years of age, having at least three years' experience in the qualification. Applicants should possess the D.P.H. and experience of School Medical work and general Public Health work is necessary.

The Officer appointed will be required to reside in the Borough, to devote his whole time to his official duties, and to work under the direction of the Council's Medical Officer of Health.

The commencing salary is £650, rising by annual increments of £25 to a maximum of £750 per annum. The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the passing of a medical examination.

Application forms can be obtained from the Medical Officer of Health, Town Hall, Wimbledon, to whom they must be returned, with copies of three recent testimonials, not later than 10 a.m. on Monday, December 19th.

Town Hall, H. R. L. MASON SMITH, L.L.B., Town Clerk, Wimbledon, SW 19, November 29th 1938.

COUNTY BOROUGH OF OLDHAM

MUNICIPAL HOSPITAL

RESIDENT ASSISTANT MEDICAL OFFICER

Applications are invited from registered Medical Practitioners for the post of Resident Assistant Medical Officer. Applicants must not be over 45 years of age.

Salary £200 per annum, with board, residence, and laundry.

Candidates should be unmarried. The appointment will, in the first instance, be for a period of six months. The successful applicant, however, will be eligible for reappointment for a further period of six months.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

The hospital comprises 375 beds, with facilities for training experience in medicine, surgery, midwifery, and diseases of children.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Oldham, and should be returned, endorsed "Resident Assistant Medical Officer," as soon as possible, but not later than 9 a.m. on Wednesday, December 28th, 1938.

Town Hall, THOMAS ALLEN, Town Clerk, Oldham, December 5th, 1938.

NORTHWICH RURAL DISTRICT COUNCIL.

NORTHWICH URBAN DISTRICT COUNCIL, WINSFORD URBAN DISTRICT COUNCIL, MIDDLEWICH URBAN DISTRICT COUNCIL.

APPOINTMENT OF WHOLE-TIME MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Practitioners, not exceeding 45 years of age, who are also registered in the Medical Register as holders of a Diploma in Sanitary Science, Public Health, or State Medicine, for the above appointment.

The appointment will be made subject to the approval of the Minister of Health, the provision of Section 110 of the Local Government Act, 1933, and the Sanitary Officers' (Outside London) Regulations, 1935.

The Officer appointed will be required to commence his duties on April 1st, 1939, and devote the whole of his time to the performance of the duties of the office, which will include the Superintendence of the Joint Isolation Hospital.

He will not be permitted to engage in private practice as a Medical Practitioner, will be required to enter into an agreement with cash Authority, and to reside within the area.

He will be allowed one month's annual leave. Salary £650 per annum, rising by annual increments of £25 to a maximum of £900, together with a travelling allowance of £150 per annum.

Office accommodation and clerical staff will be provided, and the Officer appointed will be expected to attend Council and Committee Meetings of the Authorities as and when required.

Each Council will designate the position as an Isolation Post under the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Applications, endorsed "Medical Officer of Health," stating age, particulars of qualifications and local government experience (if any), supported by copies of not more than three recent testimonials, which will not be returned, must be delivered to the undersigned not later than December 24th, 1938.

Candidates of members of any Authority, directly or indirectly, will be deemed a disqualification.

HAROLD GRANTHAM, Clerk of the Northwich Urban District Council, The Council House, Northwich, December 1th, 1938.

WIRRAL JOINT HOSPITAL BOARD

CLATTERBRIDGE ISOLATION HOSPITAL (100 Beds)

The Wirral Joint Hospital Board invite applications from registered practitioners for the post of RESIDENT ASSISTANT MEDICAL OFFICER at the above-named Hospital.

Preference will be given to applicants who have had experience in Bacteriology.

The Hospital is situated within easy distance of the Liverpool Medical School, and time will be allowed, when the work of the Hospital permits, for attendance at D.P.H. or other higher qualification classes.

The appointment is for one year only and is not renewable.

Salary £200 per annum, with board, residence, and laundry.

Duties to begin February 1st, 1939. Applications, stating age, qualifications, etc., and accompanied by copies of recent testimonials, to be made not later than December 15th, 1938, to DAVID BUNTING, Clerk to the Joint Hospital Board.

61, Hamilton Square, Birkenhead.

CITY OF LIVERPOOL

RESIDENT ASSISTANT MEDICAL OFFICER.

Broadgreen Sanatorium (353 Beds)

Applications are invited for the above appointment for a period of one year at a salary of £250 per annum, together with the usual residential allowances.

Candidates must possess a registered medical and surgical qualification, and preference will be given to candidates with previous hospital experience.

The post is suitable for a candidate working for the M.D.

The Sanatorium is within easy reach of the centre of the City and the University.

Candidates, either directly or indirectly, will be considered a disqualification.

Applications to be made on forms obtainable from the Medical Officer of Health, Hospitals Department, Municipal Annex, Dale Street, Liverpool, 2, to be endorsed "Resident Assistant Medical Officer," and returned to the undersigned so as to be received not later than Wednesday, December 21st, 1938.

Municipal Buildings, W. H. BAINES, Liverpool, 2, Town Clerk, December, 1938.

Telephone: TEMPLE BAR 1616 (3 Lines).

Chairman and Managing Director, Dr. J. FIELD HALL.

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges. No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. WEST OF ENGLAND—VERY ATTRACTIVE MARKET TOWN—PARTNERSHIP—A FOUR-TELEPHONIC SHARE, to commence (after preliminary assistantship) in good mixed-class practice, owing to death of senior partner. Receipts for past 12 months £2,305, including panel of 1200 and several appointments. Good house (4 bedrooms, etc., garden, garage) Rent, on lease, £77 10s p.a. Premium 2 years' purchase. Incoming partner should be keen worker and aged about 30. Scope for surgery and chance of being appointed to local hospital.

Peace in our Wolseley

MOTORING, in the broadest sense, is peaceful when you own a Wolseley.

It is not merely that it is more comfortable and easier to drive than most. Nor even that it is exceptionally well sprung and upholstered or that it is quiet and smooth running.

Wolseley ownership gives you peace of mind. Week in and week out a Wolseley does its job with the minimum of attention and with a remarkably low fuel consumption, which is very pleasant when you realise that nothing is sacrificed in performance.

And you have that comfortable feeling all the time that the re-sale value is perhaps the highest among cars to-day. Comfort, speed, "more power per pint of petrol," distinguished appearance—all these things you have in a Wolseley. But above all you have freedom from the petty worries of motoring and enjoy reliable, swift transport in comfort in a car you can afford to buy—and to be seen in.

Owning a Wolseley car is not so much a matter of money as of taste, for Wolseley cars are not expensive—prices are from £256. Dunlops, Triplex and Jackalls, of course.

Wolseley cars are British by Birth and Breeding. They are manufactured by Wolseley Motors Ltd., at Ward End, Birmingham, 8; distributed in London by Eustace Watkins Ltd., of Berkeley St., W.1, and exported by M.I.E. Ltd., from Cowley, Oxford.

FORECAST FOR CHRISTMAS

"Medium" & "Mild" in all districts

"Medium" or "Mild" the 'present' forecast for Christmas... and a very cheery one for all concerned because the fragrance of Player's is as much a part of Christmas as crackers and pies. So give "Player's"—the Cigarettes you can be sure a smoker would choose himself.... And you can please individual tastes by sending "Medium" or "Mild"; both are Cork-Tipped or Plain.

**Your patients will thank you
for recommending such a
delicious
fruit drink**

You can safely recommend Dole Pineapple Juice to patients who would like a new fruit juice in their diet. It is the pure, unsweetened juice of sun-ripened Hawaiian Pineapples, packed by the exclusive Dole Fast-Seal Vacuum-Packing Process. The typical analysis on the left shows you what Dole Pineapple Juice is composed of.

TYPICAL ANALYSIS

| | |
|---|--------|
| Moisture | 85.3 % |
| Ash | 0.4 % |
| Fat (ether extract) | 0.3 % |
| Protein (N×6.25) | 0.3 % |
| Crude fibre | 0.02% |
| Titratable acidity as citric acid | 0.9 % |
| Reducing sugars as invert sugar | 12.4 % |
| Carbohydrates other than sugars (by difference) | 0.38% |

+ + +

It is a good source of Vitamins A, B and C and natural fruit sugars. Dole Pineapple Juice has received the Seal of Acceptance of the American Medical Association Committee on Foods. Taste and test this tangy drink yourself—write us on your letter-head and we will send you a sample tin.

OBSTINATE PSORIASIS RELIEVED ★

Often, in spite of correcting faults of diet and clothing, psoriasis proves obstinate. In such cases local treatment is indicated. Sphagnol Ointment (which contains soothing, healing distillates of peat) will be found to be of assistance. It deals with the scaly eruptions and helps the growth of new and normal skin. Sphagnol Ointment, too, will be found

to be useful in the treatment of haemorrhoids and eczema.

In case you have had no personal experience of Sphagnol we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd., Dept. B.M.J.20, 21, Bush Lane, London, E.C.4.

AZOCHLORAMID N-N-DICHLOROAZODICARBONAMIDINE

... is a new germicide, extremely stable and effective in the presence of serum, pus, exudates, and other organic matter. Recommended for the treatment of infected wounds and abscesses of various kinds and degrees.

THE NECK: Carbuncle on back of neck at junction with Thorax.

Using gauze moistened with Azochloramid Solution in Triacetin 1 : 500 the wound was packed post-operatively and the dressing changed every 48 hours. Photograph, after four weeks of treatment following excision—shows the area clean with healthy granulation.

Allenburys
BEEF JUICE

In such conditions it is a primary consideration that the food should be light and unirritating. In gastric and duodenal ulceration and in the dyspepsias, Allenburys Beef Juice may safely and advantageously be given, where beef tea would often increase the pain and have a harmful effect. Because of its high protein and vitamin content, it provides a valuable means of keeping up a patient's strength.

In bottles at 1/9 and 3/- each.

Descriptive literature and clinical trial sample will be sent on application.

PRESCRIPTION for an INFANT'S PROTECTION

VITAMINS A and D—WINTER ROUTINE

10 DROPS DAILY IN THE FRUIT JUICE

Adexolin Liquid is an effective, simple and economical means of supplementing the infant's diet with vitamins A and D, an essential measure at this time of year, when sunshine is meagre and maternal reserves of the protective vitamins are low. In Adexolin Liquid, concentrates of the two vitamins are rationally balanced, building up and maintaining a strong barrier to infection by fortifying the epithelial structures and by promoting the assimilation of calcium and phosphorus (which in turn play an important part in maintaining the internal 'defence mechanism'). The daily dose of 10 drops is equivalent to twenty times as much cod-liver oil, without the fishy oiliness, excess fat, or nauseous taste. The routine of two drops in the usual fruit juice, or placed on the tongue after each feed, constitutes a powerful protection against the ills of winter. Two drops of Adexolin are also a wise addition to each feed of the bottle-fed infant.

ADEXOLIN LIQUID

Glass Laboratories Ltd., Greenford Middle. BY Reg 3434

For full particulars of the
Adexolin Liquid, see the
advertisements in the
British Medical Journal
and in the Lancet, and in the
other medical journals.

RIGOURS ARE NOT A NORMAL ACCOMPANIMENT TO INTRAVENOUS SOLUTIONS

Unless your Intravenous Solutions are kept in a state of *absolute* sterility, stability and of constant pH value, they cannot be considered *safe*. Thousands of hospitals are now leaving the responsibility of providing them with unquestionably safe Intravenous Solutions to the Baxter Laboratories, who furnish a complete and instantly available Intravenous Service of varied Solutions in their "Vacoliter" containers and ready-to-use accessories.

"Vitamin B₁ deficiency an outstanding fault in the diet of many millions of people"

(B.M.J., 16 Oct., 1937, p. 753)

The reduction in Vitamin B₁ intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent., and may be as much as 70 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B acts as a limiting factor in the maintenance of health and nutrition, and often results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, contributes to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International Units, an amount sufficient to raise a deficient diet to an optimal level.

The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamins B₂ and B₆, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B₁ activity with no addition whatsoever. Clinical sample and literature on request. Vitamins Ltd., The Bemax Laboratories, (Dept. B.74), 23, Upper Mall, Hammersmith, W.6.

Habitual Abortion and Dietary Sterility

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertiol.

FERTIOL

Wheat Germ Oil Capsules

A highly active source of Vitamin E.

A complimentary box of Fertiol Capsules and brochure sent on request.

Vitamins Ltd.,

Anti-Cold — Anti-Influenza

INOCULATION BY THE ORIGINAL VACCINE
IN TABLET FORM

BUCCALINE

Made in Switzerland by the Serum and Vaccine Institute under the supervision of Dr. G. Sobernheim, Professor of the University of Berne.

Under normal conditions Buccaline Tablets will give protection against Colds and Influenza for a period of four to six months.

The Director of the Barmelweid Sanatorium in Switzerland, Dr. Werner Jost, writes in an article appearing in the *Swiss Medical Journal* :—

"I have, in the last three years, tested Buccaline on nearly 900 people, sick and healthy. The effects appear to me so clear that the vaccine should be as generally used as possible."

Set of Three Immunising Doses:

Adults, 5/- per tube (post free). Children (over 4 years), 3/6 per tube (post free).

ACRIFLAVINE 'B.D.'

The powerful antiseptic properties of acriflavine are universally recognised and are utilised in many branches of medical and surgical practice. In addition to its issue as a pure substance, the following presentations of Acriflavine 'B.D.' are available :—

CREAM— for wounds, scalds and burns.

SUPPOSITORIES— for rectal administration.

EMULSION— particularly valuable as a perineal dressing.

SOLUTION (concentrated)— for the rapid preparation of solutions for general surgical use.

PESSARIES— for vaginal application, three sizes, for adults, children and infants.

SOLUTION TABLETS— for the rapid preparation of isotonic solutions.

A special non-toxic acriflavine is available—Acriflavine 'B.D.' (Intravenous)— for use in the treatment of gonorrhœa and various bacteræmic states.

COSOME 'MERCK'

(BRAND 'EPHETONIN' COUGH SYRUP)

for the treatment of

COUGHS OF ALL KINDS

in children and adults,
Whooping-cough in particular.

CATARRHAL CONDITIONS

INFLUENZA AND INFLUENZAL PNEUMONIA

Particularly if associated with circulatory disturbances.
BRONCHITIS—Acute and Chronic

Particularly suitable in paediatrics

"COSOME" contains "Ephetonin," "Dionin" and syrup of thyme, all three of which components exercise a distinctly beneficial action in respiratory diseases. "Ephetonin," as a stimulant of the sympathetic nervous system, dilates the bronchials and promotes expectoration. Further, it maintains blood pressure and stimulates the respiratory centre and the action of the heart. "Dionin" is effective in alleviating irritant cough and relieving pain, while the use of syrup of thyme in the treatment of coughs and other respiratory affections is well known.

Available in bottles of approximately 170 cc.

OVALTINE

IN NUTRITIONAL CRISES

WHILE the average adult is able to maintain a healthy existence on the ordinary everyday diet, there are certain periods in the life of each individual when an increased demand for the vital food elements arises. Outstanding examples are the period of adolescence, the pregnant and nursing states and the stage of convalescence after severe and lowering illnesses.

"Ovaltine" is an eminently satisfactory adjunct to the ordinary dietary at all such times. Composed of fresh, full-cream milk, eggs and malt extract in proportions adjusted to meet physiological requirements, it provides, in an agreeable form, calcium, phosphorus, vitamins and other important food elements.

"Ovaltine" is a metabolic stimulant and digestive which assists the assimilation of other foods and promotes general good health. It can, therefore, be taken regularly with advantage in place of tea, coffee, or other beverages. A noteworthy feature is its delightful taste which is appreciated by people of all ages.

A liberal supply for clinical trial sent free on request.

LIVOGEN

The Reconstructive Tonic

In addition to liquid extract of liver Livogen contains all the essential members of the Vitamin B complex, including Vitamin B₁, lactoflavine and nicotinic acid which are concerned in the physiological activity of the brain and nervous system. Deficiencies of these substances, although usually not marked, are common.

Livogen, therefore, is a valuable tonic in debilitated conditions particularly when symptoms of neuritis, neuralgia and other nervous dysfunctions are present.

★ Vesical Neck Fibrosis

ARGYROL

BRAND SILVER PROTIN

Urologists are generally agreed that vesical neck fibrosis or median bar is a late sequel of prostatic or periprostatic inflammation, which frequently responds to conservative, non-operative measures. Prostatic massage, dilatation instillations of 10-20 per cent. Argyrol solution in the bladder and special attention to possible remote foci of infection, often suffice to afford relief and thus prevent the otherwise inevitable resection or prostatectomy.

Argyrol is especially useful in the infected bladder, which generally accompanies the fibrosis, because of its unique sedative and bacteriostatic properties. The irritable bladder, with its distressing symptoms, usually makes a strikingly quick response to the soothing influence of Argyrol and soon functions normally, without pain or distress. Chemically different from all other silver products, Argyrol, although it is a mild silver protein, in fact the prototype of all

silver proteins, is in a class by itself—*sui generis*. It has never been duplicated and it is the only silver salt which does not tend to become irritating with increased concentrations.

Insistence on having the name ARGYROL on all solutions ordered or prescribed, will ensure the clinical results you expect.

Announcing

PERTUSSIS ANTIGEN (DETOXIFIED)

Lederle

THIS new form of therapy is recommended for the treatment of active cases of Whooping Cough as well as in general prophylaxis.

Free from bacterial cells, "PERTUSSIS ANTIGEN (DETOXIFIED) *Lederle*" is a departure from the usual form of vaccine therapy. Based upon a toxic principle derived from *H. pertussis*, treatment with formalin converts the toxic factor into a non-toxic substance having antigenic properties.

If used early in *treatment* or soon after exposure, the immunological response is sufficiently rapid to modify or prevent, respectively, the disease in the majority of cases, as evidenced by the following—49 of 53 cases treated during the first or second week did not develop whooping or vomiting.

Of 70 cases treated during the third or fourth week, 30 became symptom-free after the completion of injections, while the remainder showed marked improvement but continued to run a mild, modified course of whooping cough. Cases treated during the fifth week showed no benefit.

When used for *prevention*, only 3 out of 140 developed the disease and those 3 were mild atypical cases.

A thorough investigation

(reported in "The Analyst," 1936, Lxi, 310.)

could find no tea on the market which was free from tannin

The following facts about tea and tea tannin have been established by recent clinical and laboratory experiment:—

- [A] Tea as normally drunk is harmless and has no ill effects whatever on the human body. The amount of caffeine and tea tannin in tea is pharmacologically small.
- [B] Tea tannin is a different substance from the tannic acid of the Pharmacopœia, which is a Pyrogallie tannin, and the two should not be confused.
- [C] Clinical experiments have shown that the action of tea tannin is very much milder than that of tannic acid, and the different composition of the two tannins is proved by the fact that the tannic acid of the Pharmacopœia is about 25 times stronger as an acid than tea tannin.
- [D] Many common beverages besides tea contain similar tannins and in comparable amounts.
- [E] If there were any teas completely free from tannin, they would be almost entirely tasteless.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 17 1938

SCIATICA AND ITS TREATMENT*

BY

WILFRED HARRIS, M.D., F.R.C.P.

Consulting Physician, St. Mary's Hospital; Physician, Maida Vale Hospital for Nervous Diseases

Sciatica, or pain which is referred along the course of the sciatic nerve, may arise from a great number of causes. One of the commonest is a perineuritis of the sciatic sheath in the region of the sciatic notch where the nerve escapes from the pelvis into the buttock, which may be due to the spread of rheumatic or gouty fibrositis of the lumbo-sacral fascia or lumbar muscles, known as lumbago.

The nerve trunk may be the subject of a neuritis from toxic causes, such as diabetes, lead, arsenic, etc., or an infective neuritis from dental sepsis. I have known it produced by a direct chill to the buttock from sitting on a cold wet seat; and trauma to the buttock from a fall in the hunting field or prolonged pressure from lying on a hard surface, as in coma due to mine explosions, will produce it.

Types of Sciatica

One may speak of two types of sciatica, high sciatica and low sciatica, the latter form being due to lesions in the neighbourhood of the sciatic notch, as already referred to. In this type the Achilles jerk is often lost, and there may be a tendency to lean over towards the affected side. High sciatica would be due to lesions in the neighbourhood of the intervertebral foramina around the fourth and fifth lumbar nerves, due to rheumatic or septic inflammation, or even to osteo-arthritis. In this form the Achilles jerk is usually unaffected, as this reflex is concerned in the first sacral root, and there is often well-marked contralateral scoliosis in which the hip on the affected side is thrown outwards and the patient leans away from that side. In these cases forcing the body into an erect position causes pain down the affected leg. In this type of case, unless contractures have developed after many months of suffering, the scoliosis disappears on lying flat, especially if the legs are pulled down, with the body held to resist the pull. This disappearance of the scoliosis without producing pain is probably due to the nerve roots no longer being pressed on at the intervertebral foramina, and is a demonstration that the contralateral scoliosis apparent on standing is an involuntary posture assumed by the patient to relieve the pressure at these points and is not caused by arthritis of the intervertebral articulations, as asserted by Putti.

* Read in opening a discussion at a joint meeting of the Sections of Neurology and Psychological Medicine, and Orthopaedics and Fractures at the Annual Meeting of the British Medical Association, Plymouth, 1938.

Aetiology

Pain in the sciatic distribution may be caused by many forms of bony abnormality, such as sacralization of the fifth lumbar vertebra, or a separate first sacral piece which may be called a sixth lumbar vertebra. Sacro-iliac subluxation from trauma or due to the flat back acquired on an operating table under a prolonged anaesthetic is another cause of pain in the region of the lower part of the buttock which may be associated with pain down the back of the thigh. This pain, which is sometimes agonizing, may be due to the lumbo-sacral cord being pressed on by the sharp edge of the sacrum at the sacro-iliac joint. These cases are sometimes dramatically cured by manipulation under an anaesthetic.

Bony disease in the pelvic bones, such as Paget's disease affecting the ischium, or other tumours of the pelvic bones or in the pelvis, secondary malignant growths in the lumbo-sacral spine, or tumours in the lumbo-sacral cord or cauda equina, have all to be considered in the diagnosis of obscure cases of pain in this region. What may be called malignant sciatica is by no means an uncommon sequel of carcinoma of the breast.

In the diagnosis of these cases care must be taken to examine for muscular wasting in the leg or thigh, for patches of anaesthesia, or for alterations of the deep reflexes. If the knee-jerk is diminished or lost we know at once that the case is not a true sciatica, but that the anterior crural system is involved. Lumbar puncture and examination of the cerebrospinal fluid may give a clue in tumours low down in the spinal canal involving the sacral cord or cauda equina. Besides the more usual forms of tumour such as fibroma or sarcoma, cysticercus, lipoma, and chronic arachnoiditis, with cystic formation, may be mentioned, and herniation of the body of an intervertebral disk. These will scarcely show in radiographs, except with careful lipiodol pictures. The pressure may be found to be below normal, and there may be other evidences of spinal block, with high protein content in the fluid.

Tuberculous caries of the ilium or sacrum, with or without psoas abscess, or intrapelvic pressure from a high forceps delivery in childbirth may press upon the nerve and cause severe dropped foot, with anaesthesia of the sciatic distribution. I saw one such case, with left sciatic paralysis, in which delivery was accomplished under an anaesthetic. There was also paralysis of the musculo-

spiral nerve on the right side from arm pressure against the edge of the table. The diagnosis which had been sent up with the case to hospital was "crossed paralysis."

Osteo-arthritis of the hip-joint may cause pain not only in the region of the hip and knee but even down to the ankle, and true sciatic neuritis may result from spread of the inflammatory reaction around the hip-joint to the sciatic nerve, which passes only half an inch behind it. In all cases it is advisable to examine the movements of the hip-joint to make sure that they are free. In many cases of sciatica, whether of the low or the high type, the pain will be increased by stretching the nerve, as by flexing the hip with the knee straight. This sign is usually known as Lasègue's sign, which is precisely the same as Kernig's sign in meningitis. Patients suffering from sciatica usually prefer to lie on the opposite side, with the affected knee slightly drawn up, and a pillow should be given to separate the knees, with a curved support under the bedclothes to prevent the weight pressing on the foot.

Points in Diagnosis

There are many points, therefore, to attend to in the diagnosis of a case of apparent sciatica when first presented: knee-jerks and Achilles jerks should be compared with those on the other side, muscular wasting should be looked for, and the sensation also tested. The hip-joint should be moved and the nerve stretched gently to look for increase of pain, and a rectal examination is generally advisable. If the knee-jerk is diminished, tabes dorsalis may be thought of and the pupils examined, or alcoholic or diabetic neuritis looked for.

Tenderness over the notch in the buttock and along the upper part of the nerve is common in the low type of sciatica, but usually this is not present in high sciatica with contralateral scoliosis. There is no wasting of muscles in the common rheumatic types of sciatica, either of low or high type, except in the very chronic cases of many months' or years' duration, when the nerve may be actually shrunken and cord-like. In such extreme cases it will be necessary to cut down upon the nerve and scarify it longitudinally in order to free the adhesions.

Treatment

The treatment of sciatica will vary according to the type. In the low type of sciatica, especially when there is tenderness at the notch and the patient leans towards the affected side, rest in bed should be insisted on, and local heat by radiant-heat lamp or infra-red rays may give considerable relief. Some practitioners favour short-wave radiotherapy, and I have seen this successful when most other treatments have failed, but as a rule I have not found diathermy to be of much service. Galvanism often aggravates the pain in the acute stage of sciatica, though in the chronic stage it sometimes may prove valuable. Moist hot packs, such as cataplasma kaolini or mud packs, or mud baths at Harrogate or at the Continental spas such as Pistany or Acqui, may be given in chronic cases where the patient is able to walk. The very acute cases must be treated in bed. Local applications of liniments, such as A.B.C. or methyl salicylate, may be applied in addition to hot packs, and for the acute pain analgesics should be used freely. Compound aspirin tablets with or without codeine, and in more severe cases pyramidon, heroin, and medinal cachets, or actual injections of omnopon or morphine, may be necessary to tide the patient over the severe attacks of pain and to produce sleep.

Two methods of massive injection of novocain and saline may be used with great benefit in a large proportion of cases, and sometimes rapid cure may follow their use. In the low type of sciatica such as that following lumbosacral fibrositis, in which there is tenderness on pressure over the nerve in the buttock and at the notch, the injection may be made into the nerve trunk itself at the notch and a second injection at the level of the small trochanter. This is not the place to give the details of the method of injection, but 2 c.cm. of 2 per cent. novocain are first injected into the nerve and then 80 to 100 c.cm. of normal warm saline. A second injection may be of service a few days later. This method of injection of the nerve was first used in 1902 by Lange (1904).

Another method of epidural injection was advocated in 1901 by Sicard (Sicard, 1921)—by injection of novocain and saline up to 100 c.cm. into the sacral canal through the sacro-coecygeal foramen. Owing to the sacral canal not communicating with the intrathecal space, which ends at the level of the lower end of the first piece of the sacrum, the saline forces its way upwards outside the theca, stretching the sacral and even the lumbar roots as they emerge. This method is probably of greater service in the high form of sciatica. Other solutions are sometimes used, such as 10 to 20 c.cm. of a 40 per cent. solution of antipyrine, as Feiling (1928) recommends.

For obstinate chronic cases Dogliotti's method of intraspinal injection of absolute alcohol has been recommended; but it is a dangerous treatment, and should not be undertaken by a novice. I have used it with success in a case of eight years' severe constant pain and misery due to sacralization of the fifth lumbar vertebra, procuring several months' complete relief of pain, though for the first fortnight sphincter paresis was present.

Fixation of the limb with a Liston splint along the side has been advised, but I do not recommend it, as patients usually cannot bear to be kept in a fixed position for many hours. Another form of fixation is sometimes of benefit—namely, a plaster jacket, applied with the patient slung up by the armpits and head so as to stretch the spine, the plaster bandages being applied from under the armpits to just below the level of the great trochanters. The advantage of a plaster jacket is that the patient can get about and even attend to his business, in reason, though it has certain obvious disadvantages. An alternative is keeping the patient confined to bed, with the feet raised on six-inch blocks, and extension to the spine applied by means of leather anklets attached by cords running over pulleys fixed on the foot of the bed to separate shot-bags weighing 6 to 8 lb. A certain amount of counter-extension by padded axilla rings tied to the head of the bed will probably be necessary in addition to the raising of the foot of the bed on blocks. This method of extension does not preclude a certain amount of lateral movement or rotation by the patient, and the weights are easily detached at night or for toilet purposes.

If a plaster jacket is applied it is very important that proper extension to the spine, including the neck, should be arranged for during the whole period of the fixing of the plaster and its setting. This is best done by the use of Sayre's extension apparatus, with tripod and pulleys fixed to leather bands for the chin and occiput, and axilla pads. The patient is slowly and carefully raised by the pulleys on to his toes, most of the weight being taken by the arms. If raised in this way the patient can remain quite comfortably semi-suspended while plaster bandages are applied from axillae to trochanters over a

stockinet vest, the bony prominences, such as the iliac crest, being well padded with adhesive felt, known as elephant plaster.

Conclusion

Briefly, therefore, the treatment of an acute severe sciatica should be complete rest in bed, with local anodyne liniments and cataplasma kaolini, and sometimes local heat by infra-red rays. Analgesic drugs must be given, such as aspirin, phenacetin, and caffeine tablets, with or without codeine or opium, and even morphine or heroin injections may be required for a few days. Sleep may be obtained by the use of 7½ grains of medinal with two veganin tablets. Massage must never be used in the acute stage. Later in the more chronic stage massage may help, and galvanism, diathermy, or local heat should be tried. If these fail, massive injection of the nerve or epidural injection by novocain and saline, and extension by weights attached to anklets, with counter-extension at the axilla, should be tried. If these give only temporary relief, it may be advisable to fix a plaster from the axillae to the trochanters so that the patient may be able to get about and attend to a certain amount of business.

INTERVERTEBRAL DISK LESIONS AS CAUSE OF SCIATICA*

BY

JOSEPH S. BARR, M.D.

Boston, Mass.

(WITH SPECIAL PLATE)

A symposium such as this, which brings before us the experience of various men gained from the laboratory, the operating theatre, and the office or dispensary, is a valuable method of integrating our expanding knowledge concerning sciatica. It gives me particular pleasure to open the discussion, and I am deeply sensible of the honour conferred upon me.

For our purposes we may define sciatica as a symptom characterized by the complaint of pain in the posterior thigh and postero-lateral calf. You will note that I do not call it neuralgia, neuritis, or radiculitis, nor do I state that it is pain in the course of the sciatic nerve. It is presumably peripheral pain in the regions supplied by the sciatic nerve, due to irritation of the nerve or of any of the roots of the lumbo-sacral plexus which form the nerve. It must be obvious to all but charlatans and quacks that there are many causes of sciatic pain, the mere enumeration of which is tedious. The actual pathological change present in many, perhaps most, of the clinical cases of sciatica is unknown. It is quite probable that further advancement in our knowledge of this condition will come chiefly from increased experience of the actual pathology present and not from theoretic considerations or didactic therapeutic tests. A search of the literature reveals a plethora of cures and a sad dearth of know-

ledge as to what is being cured. There is one group of patients whose sciatica we have come to recognize as being due to the pressure of intervertebral disk tissue displaced posteriorly against one or more roots of the cauda equina. It is of this pathological entity that I wish to speak.

Anatomy

A normal intervertebral disk is composed of a semi-fluid gelatinous central nucleus pulposus which is encircled by a ring of dense coarse fibrous tissue, the annulus fibrosus. The annulus is intimately attached to the cartilaginous end-plates of the vertebrae immediately above and below each disk and also blends with the strong anterior and posterior longitudinal vertebral ligaments. Each intervertebral disk has a certain internal pressure which prevents its collapse when the superincumbent weight is placed upon it. The total amount of spinal mobility is the summation of the mobility of each of the intervertebral disks.

The function of the disk is to permit mobility of the spine, to cushion the central nervous system from trauma, and to transmit the body weight from one vertebra to another. Schmorl has made exhaustive studies of the pathological changes which occur in intervertebral disks. Extrusion of the nucleus pulposus may occur in any direction, following weakening of its surrounding tissues by developmental defect, disease, or trauma. If the cartilaginous end-plate is weakened, protrusion may occur into the vertebral body. Such lesions can often be detected by radiographs. (See Fig. 5, Special Plate.) So far as is known, these protrusions never cause radiating pain. If the annulus fibrosus is weakened by disease or trauma, peripheral protrusion of intervertebral disk tissue will occur, sometimes slowly, as a developing hernia, sometimes very rapidly, as a traumatic rupture. Schmorl found that small posterior protrusions into the spinal canal occurred in about 15 per cent. of spines examined at necropsy. He felt that they were of no particular clinical significance. Kocher in 1898 and Middleton and Teacher in 1911 reported cases of traumatic posterior intervertebral disk ruptures of sufficient size to cause paraplegia.

Neurological surgeons have recognized and removed tissue arising from intervertebral disks and pressing on the spinal cord or nerve roots, and have called these tumours chondromas or ecechondromas. It is quite probable that most of these tumours were not true new growths, but were actually displaced intervertebral disk tissue. With the advent of localizing diagnostic procedures, particularly the use in the subarachnoid spaces of iodized oil opaque to the roentgen ray, we have begun to appreciate that these posterior protrusions are not uncommon lesions and that many patients whose sciatica was previously unexplained, or who had been treated for sciatic scoliosis or lumbo-sacral or sacro-iliac strain, were in fact suffering from pressure on one or more roots of the cauda equina caused by displaced intervertebral disk tissue. We have had over eighty cases verified by operation at the Massachusetts General Hospital. Posterior ruptures of intervertebral disk tissue may occur at any level, but seem to occur most frequently in the cervical and lumbar regions. The disk between the fourth and fifth lumbar vertebrae is by far the most common site. This is probably due to the fact that this represents the apex of the anterior lumbar curve and the point of maximum stress from the superincumbent body weight. About 50 per cent. of the lumbar lesions occur at this disk; 35 per cent. at the lumbo-sacral disk. It is obvious, I think, that the symptoms and signs of a ruptured lumbar

* Read in opening a discussion at a joint meeting of the Sections of Neurology and Psychological Medicine, and Orthopaedics and Fractures at the Annual Meeting of the British Medical Association, Plymouth, 1938. Material from previously published articles by Dr. J. W. Mixer, Dr. A. O. Hampton, and the author has been freely adapted for this paper.

intervertebral disk will vary greatly, depending on its location and size. The largest protrusions cause complete occlusion of the dural sac with the usual signs and symptoms of paraplegia, partial or complete, with sensory motor and reflex changes, and partial or complete sphincter paralysis. There should be no difficulty in diagnosis or localization of such lesions. The smaller disk protrusions that press on only one or two roots are the ones which present difficulties in diagnosis and which may cause sciatic pain without demonstrable neurological changes.

TABLE

| Location of lesion: | Per cent. |
|---|-----------|
| Disk between L4-5 | 50 |
| " " L5-St | 35 |
| " " L3-4 } | 10 |
| " " L1-2 } | 5 |
| " " L2-3 | |
| History of injury: | |
| (a) Immediately preceding disability | 50 |
| (b) Latent period preceding disability | 30 |
| Total | 80 |
| Type of injury: | |
| Lifting a heavy weight | 50 |
| Falls from a height | |
| Twisting strain | 30 |
| Miscellaneous | |
| No known injury | 20 |
| Pain: | |
| Constant from onset until operated upon | 60 |
| Remissions and relapses | 40 |
| Areas to which pain was referred (unilateral 80 per cent.; bilateral 20 per cent.): | |
| Posterior and lateral thigh | 95-100 |
| Postero-lateral calf | 90 |
| Lumbo-sacral region | 70 |
| Gluteal and sacro-iliac regions | 65 |
| Lateral border of foot | 5 |
| Signs: | |
| Positive Lasègue (limitation of straight leg raising) | 100 |
| "Sciatic scoliosis" | 60 |
| Reversal of lumbar curve (kyphos or flat back) | 90 |
| Local tenderness over the lumbar spinous processes | 50 |
| Radiating pain on coughing, sneezing, or jugular compression | 40 |
| Neurological signs: | |
| Absent or diminished ankle-jerk | 50 |
| Sensory change in the extremity (anaesthesia or hypoesthesia) | 35 |
| Motor changes (weakness or paralysis) | 15 |
| Sphincter disturbance | 5 |
| Lumbar puncture: | |
| Total protein content above 40 mg. per 100 c.cm. | 85 |
| Total protein content below 40 mg. per 100 c.cm. | 15 |
| Dynamic evidence of block, whether partial or complete | 10 |
| Cytological changes in spinal fluid | rare |

This table is a statistical summary of data obtained from a study of the records of over 100 verified cases of lumbar intervertebral disk ruptures into the spinal canal.

The symptoms and signs of a ruptured lumbar intervertebral disk are so constant and characteristic that the presumptive diagnosis can often be made before radiological studies are made by the use of lipiodol. The typical case is a vigorous man in his thirties who was perfectly well until, while lifting a heavy weight, he felt something "snap" in his low back and had immediate pain in the lumbo-sacral region. Some time thereafter he developed "sciatica" in one leg, which he describes as a deep-seated pain beginning in the buttock, radiating down the posterior thigh, the postero-lateral aspect of the calf, and occasionally going into the lateral border of the foot. Coughing and sneezing, bending forward to tie the shoes, and lying face down in bed cause marked increase in the radiating pain. If an uncomfortable position is maintained for a time the leg tingles and the

foot may "go to sleep." There have been two or three separate periods of disability, the first ones relieved by rest in bed; the last one, however, has yielded to no conservative measures, including back-strapping, heat, bed rest, plaster casts, corset, and osteopathic manipulation. On examination the patient is found to stand with his trunk thrust forward and to one side, with most of his weight borne on the non-painful leg—"sciatic scoliosis." The normal lumbar lordosis has been lost, and in its place is a fixed reversal of the lumbar curve, with prominence of the spinous process of the third, fourth, and fifth lumbar vertebrae. All motions of the lumbar spine are considerably restricted by fixed involuntary muscle spasm. The patient's finger-tips cannot possibly be made to touch the floor if the knees are kept straight. The fixed list of the spine and pelvic tilt are uninfluenced by a lift under either foot. In the sitting position, the trunk can be flexed at the hips with ease, so that the chest approaches the knees, but observation reveals that the lumbar spine remains in its fixed position and goes forward *en bloc*. The list of the lumbar spine may not be as noticeable, but side bending remains restricted. (Fig 1, Special Plate.)

The patient gets into bed or on to the examining-table with extreme care. Turning over on the table is an ordeal, and he is unable to lie face down until a fat pillow is placed beneath the abdomen. In that position on palpation there is found slight but definite local tenderness in the mid-line between the fourth and fifth lumbar spinous processes or at the lumbo-sacral junction. There may be a little tenderness at the sacro-sciatic notch on the affected side. Inspection reveals some atrophy of the buttock, thigh, and calf of the painful side. The ankle-jerk is usually absent on the painful side, normal on the other. The other reflexes are all normal. No definite sensory or motor changes are made out. Straight leg raising can be carried through an arc of 70 degrees on the non-painful side and 20 to 30 degrees on the painful side. An attempt to force the leg upward beyond this point causes sharp increase in the sciatic pain. A history and physical examination similar to this suggest strongly that the diagnosis is posterior rupture of one of the lower lumbar intervertebral disks. The usual antero-posterior and lateral radiographs are of little diagnostic aid. They may be entirely normal, as the displaced disk tissue casts no x-ray shadow and the intervertebral spaces may be normal in width, the volume of the displaced tissue being too small to cause apparent narrowing. A definitely narrowed space between the fourth and fifth lumbar vertebrae is of some diagnostic importance when present. A narrow lumbo-sacral interspace occurs about as frequently as other congenital abnormalities, such as sacralized transverse processes and spina bifida, and should be considered as an incidental finding. The scoliosis and kyphosis noted clinically are also seen on the radiograph.

The next step in diagnosis is the lumbar puncture, which should be done as low as possible, preferably at the lumbo-sacral interspace. The first 2 c.cm. of fluid removed should be sent as a separate specimen for determination of the total protein. After careful manometric tests to rule out dynamic block further fluid is withdrawn for cytological study and for Wassermann and colloidal gold tests. A total protein higher than 35 or 40 mg. per 100 c.cm. is confirmatory evidence that the pathological process is intraspinal. We have a few proven cases in our series which have had a normal total protein, but the average figure has been above 60 mg. per 100 c.cm.

As the lesion is usually at one of the two lowest intervertebral disks, the lumbar puncture needle is seldom

placed caudal to it, and it is rare to find any dynamic block. The "reverse Queckenstedt" test described by Love may be of some diagnostic significance.

Examination with Iodized Oil

The radiological examination after the injection of iodized oil is the most important step in the diagnosis. The lesion can be accurately localized and readily demonstrated on the radiograph. It is necessary that the examination be done with the proper technique. In a series of over 150 cases we observed no permanent ill effects which could be attributed to the use of iodized oil in the spinal subarachnoid spaces. It is important to use oil that shows no deterioration—that is, no liberation of free iodine. It should be of a very light colour. (Fig. 3, Special Plate.)

One ampoule (5 c.cm.) of iodized poppy-seed oil is injected into the subarachnoid lumbar canal. A satisfactory examination cannot be made with smaller quantities. A delay of a few hours to two or three days between the injection and the radiological examination allows time for the oil to fill the root sheaths and permits better visualization of any defect in filling. It may be necessary to give the patient appropriate drugs for the relief of pain so that he can co-operate in the examination. The equipment for the examination consists of a tilting table for screening and a quick change-over switch so that instantaneous films can be taken. The usual equipment may, however, be used with fairly good results in the examination of the lumbar area. The advantages of films taken in this way cannot be overestimated. Before the examination is begun the patient is allowed to sit up for a few moments in order to collect the iodized oil as one mass in the sacral cul-de-sac. He is then placed facing the table in the upright position, and by manipulation of the table under radiological control the oil is forced to flow slowly up and down the anterior aspect of the subarachnoid spaces when the patient is tilted to the horizontal or the Trendelenburg position. Particular attention is directed towards maintaining the iodized oil in a single mass, and it is possible by this method to place the small quantity of iodized oil in practically any portion of the lumbar canal. Since the lesion to be demonstrated is a small anteriorly placed extradural nodule at the disk levels, the iodized oil must be brought into contact with the anterior dural surfaces, and in order to do this the patient must lie face down on the table. If a questionable filling defect is observed, repeated efforts are made to obliterate it either by turning the patient from side to

side or by repeating the tilting process. A constant filling defect in any region is recorded by serial radiographs taken at various angles of rotation of the patient. The upper dorsal area is not examined when the patient has no symptoms referable to that portion of the spinal canal. It is possible that this fact may account for the infrequency of some of the untoward reactions attributed by others to the use of iodized oil. The examination of the upper dorsal area is, however, carried out, when indicated, in the same manner as the examination of the upper lumbar and lower dorsal areas. Care should be taken to prevent the iodized oil from entering the skull, and this can be done by examining the cervical area with the patient in the face-down and lateral positions only.

Interpretation of Radiographs

A correct understanding of the results of radiological examination is dependent on an accurate knowledge of the anatomy of the cauda equina and the nature of the lesion to be demonstrated. The anatomical considerations are beyond the scope of this paper, and only typical examples of the filling defects produced by the shadow of the contrast medium can be discussed. The posterior rupture of the intervertebral disk which produces unilateral symptoms consists of a rounded nodule 1 cm. or more in diameter. This nodule lies just lateral to the strong central portion of the posterior longitudinal

ligament and is directed towards the lamina of the vertebra, usually just opposite the articular facet. It produces an indentation or filling defect in the column of iodized oil, best seen in the antero-posterior view. Unless the defect is very large its presence is obscured in the lateral view by the dense iodized oil lying in the normal side of the canal. The defect is often crescentic or dog-nose in appearance. (Fig. 5, Special Plate.) Minor pressure defects only seen in the lateral view probably represent the normal physiological bulge of the intervertebral disk and have no clinical significance.

Large ruptures may produce a complete or nearly complete block to the flow of the iodized oil, and the appearance may simulate that of an intradural tumour. (Fig. 4, Special Plate.)

Ruptures at the level of the lumbo-sacral disk are more difficult to demonstrate than those higher up, as the dural sac is narrower and smaller here than elsewhere, and so only a small filling defect may be produced by a relatively large protrusion which lies laterally and exerts pressure chiefly on the extradural portion of the nerve root.

LEGENDS FOR ILLUSTRATIONS IN SPECIAL PLATE

FIG. 1.—Photographs of a patient with lateral list (sacro scoliost) and abnormally flat lumbar spine seen in majority of cases of sciatica due to intervertebral disk rupture.

FIG. 2.—Actual appearance of a ruptured disk at operation. The laminae of two vertebrae have been removed, the dura has been opened, and the roots of the cauda equina retracted, exposing the nodule of disk tissue over which a nerve root is riding.

FIG. 3.—Drawing of x-ray appearance of a normal spine after complete filling of the subarachnoid space with iodized oil. The extradural course of the nerve roots is indicated by the dotted lines. The point of exit of each root can be identified by the axillary pouches marked A. Note that a ruptured disk at L4-5 will press on the fifth lumbar root but cannot involve the fourth root.

FIG. 4.—A ruptured disk may cause a complete block as illustrated by this case. The patient's original complaint was unilateral sciatica. There were only minor motor and sensory changes. She was completely relieved by removal of a large posteriorly displaced disk fragment.

FIG. 5.—A well-defined characteristic filling defect in the lipiodol column at the level of the L4-5 intervertebral disk. Note the obliteration of the axillary pouch. A ruptured disk fragment 1 cm. in diameter pressing upon the left fifth lumbar root was found at operation.

FIG. 6.—Antero-posterior film showing an hour-glass constriction of the lipiodol column which was found at operation to be due to a markedly thickened or hypertrophied ligamentum flavum. The patient's symptoms and clinical examination were very similar to the ruptured disk group.

FIG. 7.—Antero-posterior and lateral films showing irregular filling and partial block which was found at operation to be due to chronic adhesive arachnoiditis. The defect is not directly opposite the intervertebral disk, and appears to be intradural.

Clinical Course and Operative Treatment

The pathological studies of Schmorl have shown that the normal intervertebral disk mechanism is often disrupted and that extrusion of disk material may and does occur in many patients without causing symptoms. It is only when sufficient disk material is displaced posteriorly into the spinal canal to cause one or more roots of the cauda equina to be pinched that symptoms arise. It is doubtless true that many patients with this lesion are relieved by conservative measures. I have under observation one patient with a disk lesion, proved by lipiodol examination, who is perfectly comfortable if the spine is immobilized in a back brace or plaster jacket, but is incapacitated by severe pain if the support is discarded. If the pressure on one or more nerve roots is marked there will eventually be degeneration of the pain fibres and this symptom will disappear. As Forster has shown, this may entail no peripheral anaesthesia, as section of at least two adjacent roots is necessary if anaesthesia in the dermatome is to be demonstrated. Manipulation of the back or forced straight leg raising under anaesthesia might relieve the pain of a ruptured disk by stretching and paralyzing the pain fibres of the involved nerve root. There is danger, however, of precipitating a paraplegia by injudicious manipulation. This has occurred in two of our cases, one manipulated by an osteopath, the other by a qualified practitioner who thought he was dealing with a sacro-iliac subluxation.

Laminectomy without removal of the protruding mass of disk tissue might relieve symptoms by taking away one limb of the "nut-cracker" which is pinching the nerve root. Spine fusion, if done in a pain-free interval, might prevent recurrence of symptoms and, indeed, has probably been done many times on unrecognized cases of intervertebral disk lesions. Laminectomy and removal of the ruptured protruding portion of the disk is certainly the logical treatment for this condition if conservative non-operative methods fail. (Fig. 2, Special Plate.)

The operative removal of a ruptured disk requires laminectomy followed by a transdural or extradural removal of the disk fragment. If the lesion has been accurately localized by radiological examination the laminectomy need sacrifice no more than one or two laminae on one side of the spinous processes. The articular facets are saved if possible. The dura is usually opened in order to inspect the nerve roots and to remove the iodized oil. The ruptured fragment of disk tissue is generally found lying free beneath the posterior longitudinal ligament and compressed into a rounded mass, which can be seen to displace one or more nerve roots. Usually the most lateral root, anchored at its point of exit from the dura, rides directly over the mass. The root pressed upon may be flattened, and above the point of pressure there may be engorgement of the blood vessels and swelling of the root due to oedema. The larger ruptures may show complete occlusion of the dural sac and lack of pulsation of the dura below the point of pressure. When the posterior longitudinal ligament is incised the mass can be grasped by an Allis forceps and withdrawn. It tends to unroll, and looks like a piece of fascia or tendon when removed. A sinus which leads into the depths of the intervertebral space can always be demonstrated at the site of removal. When the extruded mass is taken away the displaced roots are seen to fall back into normal position.

There is a definite problem as to whether the spine should be fused over the laminectomized area. If an

articular facet has been sacrificed, and if the patient is one who will on recovery lead an active life, we feel that the spine will be stronger if bone chips, supplemented with an osteoperiosteal graft removed from the tibia, are used to bridge the defect. This procedure need not prolong the operation more than a few minutes, as the tibial graft can be removed by a second team at the same time as the laminectomy is being done. The wound is closed in the usual fashion, after careful haemostasis, without drainage. If there has been no fusion the patient is kept recumbent in a firm bed for two or three weeks. If fusion has been done the patient is kept recumbent for four to eight weeks and a brace or jacket is continued for three to six months. Proper physiotherapy aids restoration of correct posture and muscular tone.

When examined microscopically the removed disk fragments may be found to consist wholly of normal nucleus pulposus or a fragment of annulus fibrosus, or of the elements of both. They in no way resemble chondromas or other neoplastic tissue.

Differential Diagnosis

As noted earlier in this paper, the typical case of ruptured intervertebral disk has a rather characteristic history and shows definite physical signs. The difficulty is that the mechanical low back strains often have this identical clinical picture. I have seen cases diagnosed as lumbosacral or sacro-iliac strain after careful examination by various clinicians of the highest repute—cases which were later found to arise from pressure of displaced intervertebral disk tissue on one or more roots of the cauda equina.

Almost every author, in his discussion of the differential diagnosis of low back pain and sciatica, stresses the necessity for ruling out cauda equina tumour, and details the cardinal reflex, motor, and sensory changes which accompany pressure on the cauda equina. A ruptured intervertebral disk may cause enough pressure on the cauda equina to produce obvious paralysis, anaesthesia, etc., but the majority of these cases have protrusions so located and of such size that only one nerve root is pressed upon and the only symptom is referred pain, all objective neurological signs being absent. We cannot accept a negative neurological examination as proof of the absence of this lesion. Neither can we accept the statement that a given case is a "classical picture" of sacro-iliac or lumbosacral strain. In either instance the actual pathology may be intervertebral disk pressure on a nerve root. As Love has said, "There are no physical, neurological, or orthopaedic signs which are found alone in cases of protrusion of intervertebral disks. All of the known signs may also be found in other conditions."

There are certain organic lesions of the low back other than tumours, probably rarer than rupture of an intervertebral disk, that need to be considered in the differential diagnosis. Arachnoiditis, characterized by matting together of the roots of the cauda equina, may cause intractable low back and sciatic pain, which is usually bilateral. Subarachnoid haemorrhage following trauma may be the cause of this condition. Lumbar puncture, if done in the area of fibrosis, will show the dynamic alterations of a complete or incomplete block, or it may be impossible to obtain fluid unless the needle is inserted at a higher level. The lipiodol examination is not characteristic, but an incomplete, very irregular slow filling or a block with an irregular margin is usually noted. (Fig. 7, Special Plate.)

A thickened ligamentum flavum may so constrict the dura as to produce pressure on one or more roots of the cauda equina. Spurling has recently drawn attention to this condition. Can it be due to localized extradural haemorrhage producing fibrosis and thickening of the ligament? Lipiodol examination usually reveals a constricted hour-glass type of filling defect on the posterior and lateral aspects of the spinal canal. (Fig. 6, Special Plate.)

Results

A total of eighty-three cases of lumbar intervertebral disk ruptures producing sciatic pain have been operated on at the Massachusetts General Hospital up to June, 1938. The immediate complete post-operative relief of the sciatic pain is commented upon by practically every patient.

The operation is of considerable magnitude, and should be undertaken only by competent surgeons after a thorough trial of conservative methods or after demonstration of the presence of a dangerous amount of pressure on two or more nerve roots. There have been two deaths in our series; both of these patients had severe irreparable nerve damage from large ruptured disks. There are three known failures. The rest of the patients are either entirely well or are very markedly improved.

Summary

Rupture or herniation of lumbar intervertebral disk tissue into the spinal canal causing pressure on one or more roots of the cauda equina is a well-established clinico-pathological entity, and is the cause of intractable sciatica in many cases. The lesion can be accurately localized by radiological examination after injection of iodized oil into the subarachnoid space. Laminectomy and operative removal of the extruded disk fragment give prompt and complete relief of symptoms in most of the cases.

ORTHOPAEDIC ASPECTS OF SCIATICA *

BY

W. A. COCHRANE, F.R.C.S.Ed.

Lecturer in Orthopaedic Surgery, University of Edinburgh

In cases of sciatica a careful climinative diagnosis leaves a group which is essentially orthopaedic. The physical examination is very important, and represents skilled interpretation of an aggregation of indirect signs which, taken together and supported by an understanding of the local anatomy and bodily statics of the part, can often point to a definite orthopaedic conclusion in the individual case and determine the proper treatment. This is the more likely to be the case if the examiner is able to interpret properly the evidence of stereoscopic films of the low back and pelvic joints.

Vulnerability of Fifth Lumbar Nerve

Orthopaedists try to explain sciatica largely on the basis of referred pain from the sacro-iliac and lumbo-sacral joints and their supporting ligaments. There is also the consideration which Putti has given to the funicular portion of the fifth lumbar nerve as it lies in the foramen. Situated as it is in this fibro-osseous canal, the fifth root, surrounded by a thick venous plexus, practically fills it. The walls of the canal are bounded posteriorly by the posterior spinal articulation, antero-internally by the intervertebral disk, and postero-externally by the lumbo-sacral and ilio-lumbar ligaments. The dorsal primary division of the nerve turns backwards to supply the sacrospinalis muscle, and in its course runs close to the lateral aspect of the posterior articulation, supplying the joint capsule itself. These relations make it possible to assert that the fifth lumbar nerve is in a position of peculiar vulnerability, as it may be affected by the action of trauma of the low back on the lumbo-sacral articulations and by inflammation of them also. It may also be affected by prolapse of the disk or by change in shape and size of the canal secondary to displacement of the fifth lumbar vertebra on the sacrum or to degenerative changes of the intervertebral disk. The slight margin of safety present in the asymptomatic individual by reason, I consider, of the competency of the normal muscular support is further jeopardized by anatomical variations of the lumbo-sacral region, which either cause increased motion at the expense of stability or, by reason of their asymmetry, produce abnormal stresses. In this connexion it is of interest to note that Steindler found anatomic variations in the lumbo-sacral region in 37 per cent. of a large group of cases of sciatica referred to the orthopaedic service.

Circumstances Leading to Sciatica

It may be submitted, then, that many cases of sciatica have their explanation in the operation of a chain of circumstances consisting of: (1) the special anatomic form of the patient, who is either of the unduly heavy or unduly slender build; (2) functional decompensation of the supporting structures of the low back, mainly muscular, often added to by advancing age, unsuitable occupation, increasing weight, debility, and a toxic factor, and leading to faulty posture with exaggeration of the normal lumbo-sacral angle. Such faulty and imperfect use, combined with degenerative changes in the disks and the presence of

G. Bertoni and B. Melli (*Rif. med.*, 1938, 54, 1526), who record twelve illustrative cases in patients aged from 12 to 35, state that Donaggio's reaction is performed as follows. If a certain quantity of ammonium molybdate is mixed with an equal quantity of normal filtered urine or cerebrospinal fluid, boiled, filtered again, and a watery solution of a basic aniline dye, such as thionin, is added, the colouring solution is completely precipitated by the molybdate and the fluid above the precipitate soon becomes quite clear. In some conditions, however, especially typhoid fever, the urine and spinal fluid acquire the property of checking or entirely preventing the precipitation of the thionin. This phenomenon has been shown by Donaggio to occur when the fluids in question contain a larger amount of organic colloid substances than normally. In typhoid fever the reaction becomes positive at an early stage and remains so throughout the course of the infection.

* Read in a discussion at a joint meeting of the Sections of Neurology and Psychological Medicine, and Orthopaedics and Fractures at the Annual Meeting of the British Medical Association, Plymouth, 1938.

anatomical variations in the lumbo-sacral level, lays the subject open to repeated minor traumata affecting the articulations and their supporting ligaments. The trauma is often the precipitating factor, operating upon an area ill prepared to receive it. It is often a trauma which, if the individual had been a physically well-educated person posturally, would never, by reason of the functional and positional reserve of the parts concerned, have produced evil effects. No part of the body can be used wrongly without the rest of the body suffering, and, conversely, if one regards the problem only as a local one without reference to the re-establishment of correct use of the body as a whole, it is not easy to effect a permanent and satisfactory cure.

Restoration of Good Posture

In cases of sciatica, therefore, that are adjudged to be lumbo-sacral in type, regard has usually to be paid to the element of muscular fatigue associated with prolonged misuse, leading to an abnormal alignment of pelvis and lumbar spine. The low back becomes almost spastically fixed in this position, usually of increased lordosis in the subacute and chronic cases. While manipulation may assist such a case, it is often necessary and better to eliminate gravity, weight-bearing, and motion for a time by a period of several weeks of thorough rest in bed on a firm mattress. The patient lies on his back with a pillow beneath the head and knees. Thrice daily, for half an hour, the dorsal spine is thrown forward by placing a firm pillow beneath it, thus leaving the lumbar spine unsupported. Thrice daily he is rolled over, to lie face downwards on a pillow placed lengthwise beneath the trunk, and three hot fomentations, at ten-minute intervals, are placed on the low back. Weight and pulley traction of 10 lb. may materially assist in relieving the more acute symptoms. In about two weeks the muscles of the back lose their spasticity, and one may then make a posterior plaster-of-Paris shell for the trunk to lie in as a cradle. The time is then ripe for giving spinal massage, and instruction to the patient, in the lying-down position, in how to gain active conscious voluntary control of the muscles of the trunk. He is taught how actively to flatten the lumbar spine, to contract the side-abdominal muscles, and to breathe correctly, using the diaphragm with the chest elevated. He is fitted to a light back-brace which spans the lumbar curve when he gets up, and is taught how to maintain an improved posture, with a lengthened-out waist, when he stands, sits, and walks.

It needs an intelligent co-operative patient to do all this, but if the surgeon knows his business and applies the instruction himself there is usually no difficulty. The brace is discarded in due course, and the final test of recovery is the restoration of habitually good posture. One would emphasize the lack of understanding that exists in the country to-day as to what a trained orthopaedist should be able to do in the proper correlation of the structure and function of the body so far as the locomotory system is concerned. He is there to establish right use wherever there is wrong use; he must be trained, and able to apply in his practice his knowledge of the proper order in which re-establishment of correct use must be made. He must carry it out himself in the re-education of his cases, and not leave it to the physiotherapist. All phases of the treatment must be applied in their correct order. Rest without proper instruction in muscle balance later is of little value, as is the application of support while painful protective spasm of muscles is still present. Indiscriminate massage and exercises, often done

at the wrong time, are all to be avoided as entities in themselves.

In no aspect of his work may the art of the orthopaedist be exercised to greater advantage than in the case of sciatica, occurring either apparently alone or in conjunction with low back pain. It is a specialty within a specialty, a field in itself.

In sprains of the sacro-iliac joint producing sciatica manipulation followed by firm protective strapping may have to be employed, but in these cases also it is not unusual for the muscles to be poor and the posture bad. Consequently they may need thorough rest, postural re-education, and support for a time after the manipulation has done its work.

Semi-sacralization of Fifth Lumbar Vertebra

In these cases of painful semi-sacralization the treatment detailed above will often succeed. In aggravated cases the effect of really prolonged rest in a well-fitted plaster-of-Paris spica has not infrequently been successful in my experience. It may be combined with traction of about 10 lb. to the affected leg. I have had patients who remain well after ten years and more following this method. There are cases of the sort which do require operation. Frequently they have had severe sciatica associated with painful affections of both the accessory lumbo-sacral articulation and the pelvic joint on the same side. The operation of spinal fusion is usually best in these cases, but one should not be in a hurry to operate on them. Far from it: if spinal fusion is to be performed, above all it must be certain that the fusion is done with the lumbo-sacral angle in the normal position and not in extension. I have had successful results by fusing the accessory articulation by a lateral Smith-Petersen approach, as for sacro-iliac joint arthrodesis, taking out the block of bone at a higher level, opposite the accessory joint. I consider this to be the least formidable type of operation for the patient. If required, the sacro-iliac joint could be fused at the same time.

Cases of Rheumatic Type

In regard to the cases which are of true rheumatic type accompanied by rheumatic fibrositis and myositis it is possible in certain cases to effect a cure by making an incision along the line of the posterior portion of the iliac crest, to detach the origin of the muscle and fascia there, and slide them down to a lower level. Heyman has rightly pointed out that such cases may closely simulate those of sacro-iliac pain, with referred neuralgic pain in the leg. Ober's operation of division of the contracted ilio-tibial band high up at its origin is also in this category.

Conclusion

Dr. Harris has rightly pointed out the importance of not neglecting to perform a rectal examination in all cases of difficulty in the diagnosis of sciatica. I well recall a case of very severe sciatica that had eluded diagnosis in which the cause was revealed forthwith by a rectal examination; it was due to an enormous abscess in the pelvis consequent upon the recrudescence of an old healed osteomyelitis of the iliac bone, the result of a bullet wound sustained fifteen years previously.

The fact that sciatica is rare in childhood and adolescence is of decided significance in explaining its aetiology on a basis of a strong muscular reserve of support to what is, after all, potentially rather a weak

part of the body—that is, the lumbo-sacral region of the spine. The penalties of the upright position are many, and this is one of them.

I must not close these remarks without paying a tribute to the Boston school of orthopaedic surgeons for the work they have done on this subject. It is due to them, and chiefly to Goldthwait, that a proper system of examination has been established and that these cases, so far as the orthopaedic aspect of them is concerned, are now capable of scientific analysis, classification, and treatment.

THE XENOPUS PREGNANCY TEST

BY

EDWARD R. ELKAN, M.D.

(WITH SPECIAL PLATE)

The discovery of what is now known as the xenopus pregnancy test is based on experiments conducted by Hogben (1930, 1931), who observed that hypophysectomy produced ovarian retrogression, and the injection of anterior pituitary extracts ovulation, in the female South African clawed toad. Further experiments on these lines were carried out by Charles, Slome, and Zwarenstein in Capetown, and later by Bellerby, Zwarenstein, and Shapiro in London, and it is due to the collaboration of these authors that the initial difficulties which stood in the way of a standardization of the xenopus test were overcome. This is particularly true with regard to Bellerby's work on the laboratory conditions necessary for sustained reproductive activity, which work made it possible to improve greatly the reliability of xenopus as a test animal. While there has so far been no difficulty in obtaining regular supplies of these toads from South Africa our next aim must nevertheless be the breeding of xenopus in this country. Bles attempted this as early as 1905, and sporadic successes have been recorded by other authors (Bles, 1906; Bellerby, 1933; Vanderplanck, 1935; Elkan, 1938). It is to be expected that in the near future we shall have not only a standardized xenopus pregnancy test but also a standardized method of breeding this animal.

Weisman (1938) recently reviewed the tests for the detection of early pregnancy which have been devised since Aschheim and Zondek's discovery eleven years ago. Apart from the Aschheim-Zondek reaction only Friedman's technique has become widely popular; the xenopus test, though in some points superior to both the Aschheim-Zondek and the Friedman techniques, has remained more or less unnoticed despite the enthusiastic reports which have appeared in various journals in recent years. These three pregnancy tests are the only ones to deserve, in Weisman's opinion, the term "excellent." In the course of the last twelve months I have done 295 xenopus tests on 2,112 toads, and I fully endorse Weisman's judgment. Some of the objections to this test raised by earlier observers seem to have become invalid, and as the early detection of pregnancy remains important from the psychological and the gynaecological points of view a method which allows the diagnosis to be made within a few hours should be welcome.

Biological Considerations

Xenopus laevis Daud., a toad of the genus *Aglossa*, is fairly common in all the tropical parts of Africa (Fig. 1,

Special Plate). The toad is exported from Capetown, where the animal dealers seem to have no difficulty in catching as many as are required. My own experience with these exporters does not confirm fears expressed by Crew (1937) and Weisman (1938) as to the availability of the animal. So far supplies seem to be unlimited and export unrestricted, and since the animals survive the passage from Capetown to London I see no reason why they should not be shipped to any part of the country. I have at present tadpoles in my laboratory bred in an open-air tank this summer. It remains to be seen whether these tadpoles can be brought up in sufficient numbers and whether their growth is rapid enough to make the breeding of xenopus an economic proposition. My present tadpoles look very much like young fish. They stand on their heads most of the time, and feed on a mixed diet of infusoria, particularly flagellates, and raw liver emulsion, of which a little is poured into the aquarium every day.

The adult clawed toads received from Capetown vary greatly in size, the smallest ones measuring 2 inches, the largest 4½ inches, from mouth to anus. I find those of medium size most suitable for tests. The small toads are mature, but do not stand the injections so well; the larger specimens tolerate the injections well, but they require very big jars for observation. It is easy to distinguish the males from the females. They are identical in colour, but the external opening of the cloaca in the female has three labia—two dorsal and one ventral—which do not, however, form a receptaculum for semen; these labia are absent in the male (Fig. 2, Special Plate). Fully grown males do not reach the same size as fully grown females. The females also acquire a characteristic shape through the bulging lungs being pushed aside by the ovaries, which protrude on both sides of the abdomen like cushions.

The animals are easy to feed. They will accept daphnia, earthworms, newts, tadpoles (*Rana esculenta*), minced meat, or minced liver, but flatly refuse to touch bread or potatoes. It is a little difficult to say authoritatively how often they should be fed. They will certainly accept food every day, but they never show any signs of being particularly hungry, and if not fed for a week they do not seem to be the worse for it. If they grow at all in the laboratory they do so extremely slowly, even if they are well fed. It is wiser not to feed those specimens which are to be used for tests in a day or two. The animals have a short alimentary canal. They eat whenever they happen to come across anything edible, but do not seem to make much use of what they have eaten. The water becomes dirty from their excreta soon after they have been fed, and must then be changed. It does not seem to matter—at least so far as the tests are concerned—whether feeding takes place once, twice, or three times a week if only the animals are given as much food as they will accept at each feeding time.

During the cold season all the animals are kept at the laboratory in a specially constructed tank, and at a temperature of 23° to 26° C. In the summer only the animals actually needed for tests are kept in the laboratory. The others, particularly those who are having their "resting time," are kept in outdoor tanks, where they become comparatively tame; when it rains they can be seen leaving the water and climbing on to stones provided for them. Hundreds of xenopus can be kept in a comparatively small space, and since the females of this species do not make any noise their presence is not a nuisance to the neighbourhood.

I cannot yet answer a question often asked by visitors: How long do these animals live, and how often can they be used for tests? I have lost a few during the winter from a disease which I cannot diagnose; it causes paralysis of the hind legs so that the toad cannot come up to the surface to breathe, and is consequently drowned if not rescued in time. This condition affected both males, which are not used for tests, and females, but almost disappeared with the approach of the warm season. The toads frequently suffer from an infection with taenia, but I have been unable so far to ascertain if these tapeworms are the cause of these sporadic losses. Toads very rarely die in the course of a test; some of my earliest arrivals must have been used three or four times without showing any signs of weakness. I keep the toads mixed, so that arrivals of all ages are used in each test.

A statement made by Zwarenstein and Shapiro (1934) that toads which have been kept under laboratory conditions undergo a process of "desensitization" and can

desensitization takes place in these animals if properly kept, and I see no reason why toads should not be used again and again so long as they are allowed proper resting periods between tests. (See Fig. A.)

The Pregnancy Test

The xenopus test, like all other biological pregnancy tests, depends on the response of the animal's gonads to anterior-pituitary-like hormone present in the urine of pregnant women. I am not quite sure as to the correctness of the term "anterior-pituitary-like," because I have tried commercial pituitary extracts in considerable doses without obtaining a response in these toads. Further experimental work will be necessary to show if the toads react in the same way to anterior pituitary extracts, extracts from serum, and extracts made from urine. The mature female ovaries contain hundreds of eggs in various stages of development. Under the hormonal stimulus numerous eggs enter the oviducts (ovulation) and are discharged from the cloaca (oviposition). Under normal conditions these eggs, which are covered with a sticky gelatinous mass, are one by one fertilized by the male as they leave the cloaca and are then stuck on to water plants by the female. In the test the eggs fall through a platform to the bottom of the test jar, where they can easily be seen with the naked eye (Special Plate, Fig. 3).

The test proper starts with the collection of the urine. It seems wise to limit the patient's intake of fluids so far as possible on the day before collecting the specimen. She thus concentrates her own urine and thus increases the reliability of the test; no drugs should be administered during this period. Some 6 oz. of morning urine are collected in a clean—not necessarily sterile—bottle and sent to the laboratory. Here the investigator can easily determine whether his directions have been followed or not. Not infrequently the patients drink quantities of Vichy water or tea to be sure that they produce the necessary amount of urine in the morning. An estimation of the specific gravity allows these valueless specimens to be discarded. Personally, I do not expect reliable results from urines with a specific gravity below 1015; figures from 1020 to 1030 are desirable. Slight turbidity is not important, but if the urine is very turbid it should be filtered.

For the test itself untreated urine or an extract made by Zondek's alcohol and acetone precipitation method may be used. Bellerby (1933) thinks that the process of ovulation follows quantitative rules and does not depend on a "trigger action." I am not convinced that this can be accepted as a general rule, since I see every day that different toads injected with exactly the same dose of extract lay very different numbers of eggs. Crew (1936) uses extracts only and does not regard as reliable tests with untreated urine. I, too, have seen negative results from untreated urine and positive results on using extracts of the same urines, but in other cases both methods have given positive results, and I could find no constant relation between these latter results and the stages of the respective pregnancies. More experimental work is needed to clarify this point. The use of untreated urine would seem more economical, and in addition we do not know how much hormone becomes denatured in the course of the precipitation and concentration. However, since Zondek's method affords a certain means of concentration, and since we want to make the test as reliable as possible, this method seems at present the better one. This does not mean that tests with untreated urine cannot be perfectly reliable, and some laboratory workers might find it best

FIG. A.—Dissection of a female *Xenopus laevis* which was kept in captivity for over six months and then killed after having given a positive pregnancy test reaction. Note the well-developed ovaries and oviducts and the absence of any signs of degeneration of the reproductive system.

no longer be relied on after three to four weeks has since been repeated by Crew (1937) and Weisman (1938), and is one of the reasons why workers in this field have been slow in taking up this otherwise useful and reliable test. I cannot endorse this statement from my own experience. I have received consignments of toads from South Africa with the animals' ovaries in a state of quiescence. This may be identical with the state of "desensitization," but after these animals had been well kept and fed for three to four weeks they gave reliable results. Others gave reliable results from the day of arrival. A study of Bellerby's papers (1929, 1933, 1938) on the biology of these toads may explain this puzzling behaviour. In my experience no

to test untreated urine first in all cases, and to test a second time with the extract only in those cases in which untreated urine gave a negative finding.

Technique of Testing

For the test 2 c.cm. of untreated urine or 1 c.cm. of extract is injected into the lymph sac under the dorsal skin of as many female toads as one cares to use. Some observers inject into the leg or into the peritoneal cavity. The toads are slippery and difficult to hold; I find that the easiest way of dealing with them is to hold them in a coarse meshed net and to inject through the meshes. There is no immediate reaction to ordinary urine. If extract is used which still contains a trace of alcohol or acetone the toads react by secreting mucus from the skin glands in the neighbourhood of the injection. The question of the "toxicity" of the urine seems to arise very rarely. Specimens which had been in the post for several days have been tested, and while I am not sure that the hormone content remains constant in such specimens they seem to do no harm to the animals.

After the injection has been given the toads are put into test jars (Special Plate, Fig. 3), where they sit on perforated platforms, so that they have no chance of eating their own spawn. This may be an unnecessary precaution. I have left toads in their jars for days and have never seen them eat their spawn; in fact, as a reaction to the close confinement, which they seem to dislike, they vomit up everything they have eaten shortly before the test. It is for this reason that Bellerby (1929) prefers to leave unfed for a full week those toads he is going to use for tests. I have a strong suspicion, however, that the xenopus when at liberty is cannibalistic. A male and a female left in a breeding tank for a few weeks this summer produced only three tadpoles; since it is unlikely that the female should have laid only three eggs my suspicion is, I think, justified.

During the test the jars are kept at a temperature of 26° C. The shortest time I have so far observed between injection and oviposition was four hours and fifty minutes, the longest twelve hours. Figures midway between these two extremes are more usual. I have no definite proof as to whether the concentration of the hormone in the extract or the temperature at which the animals are kept during the test has anything to do with the reaction time, since of a group of toads used for one test no two ever start laying eggs at the same time. While the hormone concentration and the temperature are certainly of some importance in this respect, the animals themselves may provide a third factor which we cannot at present determine.

The eggs—little round balls, half black, half white, and of about 1 mm. in diameter—are covered with a sticky gelatinous substance. Normally these animals do not lay their eggs in bulk but distribute them over a wide area, sticking them on to water weeds one by one. In the test jar the eggs either stick to the underside of the platform or fall to the bottom of the jar. Their number varies enormously. Anything from five to six eggs upwards can be counted as a positive reaction. Tests in which only one or two eggs have been laid by one or two toads should be repeated. They will usually be found to be negative. In the absence of males these eggs are, of course, unfertilized. It should be emphasized that spontaneous ovulation in this species does not take place in captivity or under laboratory conditions. Females, even if kept under the best possible conditions, will never ovulate except in the presence of a male. It is difficult

enough to obtain fertilized eggs even if the males and females are kept in a special aquarium. After many unsuccessful attempts, I have recently succeeded in obtaining a batch of about 200 tadpoles, but I had to inject the female with pregnancy urine extract to induce ovulation.

If nothing is known about the stage of the presumed pregnancy or if the urine comes from a patient who has not yet missed her period an extract is made by Zondek's method. The technique is as follows:

METHOD OF EXTRACTION

Sixty c.cm. of filtered urine are acidulated with acetic acid and mixed in a separating funnel with enough alcohol and/or acetone to bring down a precipitate. The quantity of alcohol or acetone necessary varies from 150 to 300 c.cm. It seems that in some cases an excess of alcohol redissolves the precipitate. The alcohol should therefore be added slowly and only up to the point of maximum turbidity. The mixture is then shaken vigorously for a few minutes and centrifuged. If no centrifuge of sufficient capacity is available the precipitate may be allowed to settle; it can be separated off after thirty minutes, and must then be centrifuged thoroughly to free it from the alcohol-urine mixture. It is important to get rid of as much of the alcohol as possible because it has an unfavourable effect on the toads. It makes no essential difference whether alcohol or acetone is used to bring down the precipitate. Acetone is the more expensive, but it is useful in so far as it brings down precipitates from very dilute urines and, after centrifuging, leaves a residue much "drier" than that which can be obtained by alcohol precipitation. When the precipitate has thus been separated from the alcohol-urine mixture it is stirred up and shaken vigorously with distilled water (1 c.cm. for each animal injected) and glass beads. This mixture is again thoroughly centrifuged and the supernatant fluid is used for injection. The whole procedure takes perhaps 20 minutes. As for the choice of a centrifuge I have found that the small clinic model with a 1.16-h.p. motor is not sufficiently strong. A larger model with a 1.8-h.p. motor is preferable; this should be fitted with 50-c.cm. buckets and attain a rate of at least 3,000 revolutions a minute.

In the ordinary routine work the animals are injected within an hour of the urine being received. They are left in their test jars overnight and the results are read the next morning. During the test the jars should be kept at about 26° C.; in the absence of a suitable incubator this can be done by putting the jars back into the tank. The patient knows the result of the test in less than twenty-four hours. The animals, after the result has been read, are kept in the resting tank for a week if the test was negative, for a month in the case of a positive test.

Reliability of Xenopus Test

Among the 295 tests which I have done so far and in which 2,112 frogs were used I have not seen one clear positive that did not indicate a pregnancy. There were a few negative results which when repeated after a fortnight became positive, but I do not think that these can be regarded as failures. What we test is the hormone concentration in the patient's urine. If the urine is sent in for examination at a time when no hormone or only a trace of hormone is present the test naturally appears to be negative. Nor would it seem advisable to make the test too "sharp" by using methods of extreme concentration. The normal urine of a non-gravida contains a varying amount of anterior pituitary hormone. If the test is too "sharp" it may fall within the limits of the normal hormone concentrations, which vary in different women and are not necessarily constant in any one patient. It would seem better only to test urines from

women who have gone at least two or three weeks over the first "missed" period. By that time the concentration of hormone in the urine has always risen so far above the normal that no false negatives need be feared with the ordinary extraction method.

The tests I have performed myself are still too few to allow any final conclusions being drawn. Disregarding my first ninety tests, the results of which may have been influenced by the fact that I was learning the method, I can report that of the next 150 tests sixty-two had a positive and eighty-eight a negative result. No clear positive was found to be incorrect; of weak positive results, which as experience has shown must be counted as negatives, there were ten. Of negatives that became positive at a later date there were three.

These 150 tests were done on 742 toads. Of these, 734 survived the test without apparently being the worse for it. Eight toads died in the course of tests—four during negative and four during positive tests. A number of toads which were not counted, as their deaths obviously had nothing to do with the tests, some of them being males, died during the winter. I do not think that their number exceeded thirty.

Summary

The xenopus test allows a diagnosis of early pregnancy to be made within less than twenty-four hours.

No animals need be killed to obtain the result.

The reliability of the test does not seem to differ from that of the Aschheim-Zondek or the Friedman reaction.

The technique of this test is comparatively simple and very suitable for experimental work on the anterior-pituitary-like hormone of pregnancy.

My sincere gratitude is due to Mr. D. P. Gould of Loughton and Mr. R. Milton for their interest and helpful collaboration in my experiments with xenopus.

The Henry Saxon Snell Prize was founded to encourage improvements in the construction or adaptation of sanitary appliances, and is awarded by the council of the Royal Sanitary Institute at intervals of three years. The prize in the year 1939 will consist of fifty guineas and a silver medal, and is offered for an essay describing suggested improvements in the construction or adaptation of sanitary appliances. Particulars may be had from the Secretary, Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W.1.

USE OF THE SKIN OF THE FEMALE BREAST IN PLASTIC SURGERY

BY

J. F. S. ESSER, M.D.

(WITH SPECIAL PLATE)

As the breasts of many women and girls, particularly in countries abroad, are inclined to be too much developed, and the weight of these large glands stretches the surrounding skin, it is sometimes a great advantage to get rid of the superfluous skin, fat, and gland tissue.

Having thought this over seriously, I have for some twenty years advocated the use of this skin for various purposes to supply missing portions. The importance of this from an aesthetic point of view is generally recognized, but few people are aware of the suffering caused by the weight of these heavy glands. Even when not abnormally developed they may be so mobile as to cause serious inconvenience to their possessors, especially where sport is concerned.

Advantages of the Method

It seemed logical to me, therefore, to combine the necessity for supplying skin for surgical purposes with the advantage of reducing overdeveloped glands. I carried this idea further by using not only superabundant skin but even skin of normal breasts which could be taken away without causing any damage. One of the greatest advantages of the method is that the glands are often very mobile and the pedicled flaps taken from them can be easily brought to and be used in remote parts. In several instances I employed the skin for covering amputated stumps of the legs, even beneath the knee, as the legs and breasts can be brought into apposition, and also for plastic surgery of the hand and the arm. On one occasion I made practical use of it on a girl who was a pianist and who was unable to pursue her career because of the scar tissue occupying the whole surface of the inner part of the lower arm, the result of serious inflammation with suppuration and necrosis. After removing all the scar tissue I succeeded in making the articulations and muscles mobile, and in covering the gap completely with a large pedicled flap taken from the breast. In her case the skin of the breast was not sufficient to enable me to close the secondary gap on the gland with the remaining skin, so I had to fill in the gap with the help of an epithelial inlay. Epithelial inlay is a method I introduced in plastic surgery, and is so widely used that I need not here enter into all the details concerning it. I will only say that it consists in taking a mould, with Stent's composition, of wounds which have to be covered by free skin grafts. This mould is wrapped in a Thiersch graft and replaced on the wound exactly as it was when taken, and is kept pressed on it for a week.

The flap on the arm healed completely, and the layer of fat in the flap helped to keep the muscles and tendons of the arm mobile: these had lost their surrounding protective tissue and would have formed scars with the skin flap if the layer of fat had not separated them. The patient was able afterwards to continue her career successfully, and the breast had not suffered. The following are other cases in which the method was employed.

Case I

This patient was run over, and had lost both her legs. They were amputated above the knee-joints, and the skin could not be joined over the right-hand stump. The result was that after further healing the right stump cicatrized conically, while two inches of bone protruded. Professor Borchardt consulted me for this case.

It is obvious that it was of special importance to the patient to keep the entire length of both stumps, as a second amputation and further shortening would doubtless have seriously impaired the control of the artificial limb and the balance in walking. Though there was no chance of taking the necessary skin from the other leg, as is my usual practice, the principle of never amputating a second time in such cases was maintained.

By a coincidence the mamma afforded the necessary help. The patient gave birth to a healthy child in the hospital some months after the accident. Owing to the plentiful milk secretion the mammae were highly hypertrophic, and from their excessive prominence almost invited their use. Instead of cutting out a flap of skin for covering the amputated stump I inserted the stump deeply into the breast, after removing the outer layer by the osteotome and cutting away the scarred skin. The newly cut skin edge of the stump was sewn up to the edge of the incision in the mamma all the way round. As the length of the cut was calculated exactly, the wound was thus completely closed. Fig. 1 (Special Plate) shows the patient with the stump inserted in the mamma, after the wound had primarily healed and the plaster bandage had been removed. The skin and some of the tissue of the mamma adhered firmly all round the bone.

In a second operation, thirty-seven days after the first, almost the whole of the lower half of the mamma, including a thickish layer of glandular tissue, was cut off along with the amputation stump. This flap when sewn up was sufficient to cover the bone completely (Fig. 2). The wound in the mamma was closed by a plastic operation so that the remaining skin of the mamma and the rest of the glandular tissue were equally distributed over the new and smaller mamma. The asymmetry of the breasts could be remedied at the patient's wish later on by diminution of the larger one. It may be mentioned that the position during the process, although not exactly pleasant, was not so entirely strained and unnatural as one might imagine. The photograph in which the plaster bandage has been removed shows that since pressure was not required to keep the leg in position no tension has resulted. This is explained by the fact that the coxa only affords a portion of the necessary flexion, as the spina dorsalis, which bends easily, plays a great part in it. I should like to mention that the glandular tissue transplanted to the stump could be seen secreting milk out of the open seam for some weeks after the severance.

Case II

This patient, a girl aged 19, was run over in Amsterdam by a tramcar, and her right leg had to be amputated three and a half inches below the knee. The end of the amputation stump did not heal well, and I was called in. A tibial ulcer had appeared between the scars. I am, on principle, opposed to reamputation if it is not vitally essential, so I resected all the scar tissue and placed almost the entire mamma, pedicled at its upper and inner side, on the large wound of the stump. The girl's breast was not quite large enough to cover it, as I had previously taken away the greater part of the stump covering as far as the patella, all this skin tissue being scarred.

The great value of this operation lies in its preservation of the knee-joint for moving the artificial limb. The skin of the breast in the above cases has proved, as in other similar cases on which I operated, strong enough to bear the weight of the body supported by the artificial limb. I wish especially to call attention to the

fact that in general all transplanted skin flaps on stump ends must be very carefully treated until full sensibility of the flap has developed.

Case III

This patient was a young woman in Budapest to whose case I was called in. She had lost the middle three fingers and a part of their metacarpi, especially that of the index finger. This accident had occurred in the large cutting machine of a hospital kitchen. The wound healed, but the thumb was completely immobilized and had grown into the hand-stump. I cut away all scar tissue and made the thumb completely mobile, leaving a large wound on the stump of the hand and on the thumb. This large wound was placed in an incision made in her over-developed right breast. The hand remained there during four weeks. The result is shown in Fig. 3 of the Plate.

On several occasions I have healed large burns on the neck by means of pedicled mamma flaps, as well as various mutilation scars due to suppurated scrofulous glands or to other suppurations, and to necrosis of the tissues. It often happens that not only skin but fat and muscle tissues are destroyed by these suppurations.

It is possible to repair not only the lower portion of the face by means of pedicled mamma flaps, but also the upper part, even the whole forehead. I have successfully performed these operations, and in one case I restored the entire skin of the face, including the whole of the forehead, with a pedicled breast-flap. Even though these operations were entirely successful, I wish to point out that, technically, they are the most difficult forms of plastic surgery. On the other hand, the treatment of the chin is comparatively easy, particularly if the breast is very mobile.

In one case I was called in by Professor Borchardt, in Berlin, to operate on a woman aged 40 who had a large blue angioma which looked like a bunch of grapes covering the whole of her chin. I removed the tumour and made a new chin out of a pedicled breast-flap. The result was exceptionally good: her face became quite normal, and remained so. She was very grateful, but said how much she regretted not having met me before, as she had lost a possible chance of marrying and of having children. She also told me that she previously only went out at night, and was not admitted to a hotel for fear of frightening the guests by her appearance.

I will mention another operation, one of amputation of the arm, in which the pectoral muscle is perforated by a tunnel covered with skin procured from a pedicled breast-flap. The secondary gap is sewn together. The object of this tunnel is to hold the artificial limb in place and to move it with the help of a tunnel in the trapezius muscle. Pins must be placed in the tunnels and attached with strings to the artificial limb. If they are only to hold the artificial limb the strings are fixed to the end of it; if they are to move the artificial limb they must be fixed to the part of it which has to be moved.

Monaco.

A conference between the Minister of Health and representatives of local authorities on the Cancer Bill took place on December 7, when Dr. Walter Elliot received members of the London County Council, the County Councils Association, and the Association of Municipal Corporations. Various aspects of the Bill, both financial and administrative, were discussed, and the position of London and the other authorities which will have responsibilities under the scheme was further clarified. The Minister undertook to consider various representations which were made to him.

BEHAVIOUR OF TUBERCULOUS CAVITIES IN THE LUNG UNDER ARTIFICIAL PNEUMOTHORAX TREATMENT

BY

LAWRENCE ROBERTS, M.D., M.R.C.P.

Assistant Medical Officer, Papworth Village Settlement

AND

W. PAGEL, M.D.

Sims Woodhead Memorial Laboratory, Papworth Village Settlement

(WITH SPECIAL PLATE)

Tuberculous cavities in the lung may react to collapse treatment in several different ways. The case which follows illustrates three such reactions within the same lung.

It has been suggested by Coryllos (1936) that collapse and disappearance of such cavities are often due to obstruction of the draining bronchus, but objective evidence of this is still rare. In the present case such a sequence of events occurred, and the bronchial obstruction and the partially healed cavity were demonstrated at necropsy.

Case Report

The patient was a married woman aged 25, a housewife in a small village. She had no children. She felt quite well until November, 1936, when a slight morning cough with sputum started. Shortly after this a little blood was noticed in the sputum, but was ignored. In January, 1937, she began to feel progressively more tired and languid, and the cough became more marked. In April, 1937, she saw her doctor, who diagnosed pulmonary tuberculosis. This was confirmed by x-ray examination, and the sputum was found to be positive for tubercle bacilli. She rested at home for eight weeks, and was admitted to Papworth in June, 1937.

Her general condition at this time was fairly good. She was strongly built and of good colour, but there had been some recent loss of weight. Her temperature was normal. There was a slight cough, with two drachms of sputum a day. On examination the only abnormalities found were in the respiratory system. There was drooping of the right shoulder and diminished expansion of the right side of the chest. Impairment of the percussion note and moist rales were observed over the upper half of the right lung, with signs of cavitation in the middle zone posteriorly. Over the left lung rales were present at the apex both anteriorly and posteriorly. The sputum was positive for tubercle bacilli, and the blood sedimentation rate was 22 (Westergren; one hour).

X-ray examination (Plate, Fig. 1) showed well-marked fibro-caseous tuberculosis in the right lung with at least two cavities and many calcified foci. In the left lung there was a little infiltration in the subclavicular region. (Nothing noteworthy occurred in the left lung during the evolution of the case: for the sake of clarity, therefore, further description of the left lung is omitted.)

A right artificial pneumothorax was induced on July 9. The patient soon felt very fit and well, gained a stone in weight, and maintained a normal temperature. A little cough and sputum persisted, however, and the latter remained positive for tubercle bacilli. On one occasion there was slight haemoptysis. Fig. 2 shows the state of affairs on September 28, 1937. A new cavity (A) had appeared at the right apex opposite the attachment of an adhesion. The smaller of the two original cavities (B) seemed to have undergone concentric shrinking, but an adhesion was present here also. The large cavity (C) was smaller than before, but was surrounded by a well-marked ring of opacity. It was not clear whether this indicated an inflammatory reaction or a zone of atelectasis. The pneumothorax was continued with some

caution. During the next two months the general condition further improved, the temperature remained normal, and the sedimentation rate dropped to 11. The sputum continued, and was still positive. An x-ray film taken on November 24, 1937 (Fig. 3), showed cavity A to be larger than before; B was little changed, but C was much less obvious and the ring of opacity had entirely gone. This suggested that the opacity had been due to atelectasis, after which collapse of the cavity occurred.

In the same lung, therefore, one cavity was closing, one stationary, and a third enlarging, all under the influence of different factors. The pneumothorax was maintained and thoracoscopy was done by Mr. J. B. Hunter, as many adhesions as possible being divided. An x-ray film taken on February 24, 1938 (Fig. 4), showed the apparently excellent result of this: no cavitation could be seen in the lung at all. As is well known, however, disappearance of a cavity from the skiagram is not synonymous with healing. On March 6 rupture of the right lung occurred, followed by tuberculous pyopneumothorax. Despite treatment the patient steadily became worse, and died on May 29 of an acute bronchopneumonic spread in the left lung.

Necropsy Findings

At necropsy the pyopneumothorax was found to be due to rupture of cavity A, which was slit-like and communicated freely with the pleura by a caseous track (Fig. 5, A). The cavity measured one inch by one-eighth inch, and the draining bronchus was patent. Cavity B no longer remained, but a solid round focus half an inch in diameter was found in this situation (Fig. 5, B). Cavity C resembled a small cylindrical bronchiectatic cavity (Fig. 5, C), and at the commencement of the draining bronchus a plug was found. This was attached to the bronchial wall and filled its lumen, and projected also into the lumen of the cavity. In the left lung a pea-sized cavity was present in the upper lobe, and there was a recent bronchogenic spread in both lobes, which was the immediate cause of death.

Histologically, cavity A was thin-walled and lined by a layer of caseous material containing a few acid-fast rods. This caseous layer extended proximally into the draining bronchus at its beginning and distally along the fistula right out to the pleura. Around the cavity was collapsed lung parenchyma. This cavity therefore showed no signs of healing, but was merely relaxed following collapse of the lung. The solid round focus was devoid of air. It consisted of true caseous material, and, as already stated, was situated in that part of the lung formerly occupied by cavity B. Cavity C (Fig. 6) was small and had very thin walls, being directly surrounded by collapsed alveolar tissue (Fig. 6, A). A few pieces of caseous material were attached to the walls, and one such piece (Fig. 6, P) plugged the draining bronchus at its beginning (Fig. 6, B). Caseous bronchitis was present for a short distance beyond this plug.

Commentary

The chief interest of the case centres round cavity C. Vere Pearson (1930) pointed out the significance of bronchial obstruction in the pathogenesis of pulmonary cavities. Coryllos (1936) carried the matter further, suggesting that the most important factor in cavity healing is the closure of the draining bronchus, which leads to collapse of the cavity, absorption of the air, and inspissation of the contents, if any. Objective proof of this, however, is still rare enough to be worth recording. Gracff (1935) has reported one case of a completely healed cavity with closed bronchus, but it is impossible to say here whether closure of the bronchus or closure of the cavity was the primary event.

The value of the present case lies in the fact that a certain sequence of events was observed clinically: atelectasis—swift collapse of a cavity—disappearance; that before the sequence had reached its end-point—

that is, complete healing of the cavity—death occurred from another cause; and that at necropsy the sequence was found to be caused by bronchial plugging. Fig. 6 shows the plug in position. It consists of compact caseous material, and must have been in place for several months.

Closure of the draining bronchus is not always followed by collapse and shrinking of the cavity. Salkin, Cadden, and McIndoe (1936) concluded that this happens only when the cavity walls are not very rigid, and when the surrounding lung tissue retains enough of its elasticity. Closure of a cavity may be due to mechanisms other than bronchial obstruction—for instance, to concentric shrinking followed by epithelialization while the bronchus remains open (Pagel, 1932; Alexander, 1935).

It has often been noted, of course, that healed cavities may appear as solid or even calcified foci in the skiagram, but pathological evidence of this is not common. Graeff (1935) has reported a good example, and several others have been described by Pagel and Simmonds (1938).

The various mechanisms of cavity healing have recently been reviewed by Marienfeld (1937) and Pinner (1937).

It is instructive to note that cavity A showed no signs of healing whatever: its walls were merely relaxed following collapse of the lung. This emphasizes the fact that some parts of a diseased lung may steadily improve under collapse treatment, while others may remain actively diseased and lead to the death of the patient.

Summary

The recorded case of treatment by artificial pneumothorax shows: (1) Collapse and shrinking of a cavity due to obstruction of its bronchus. (2) Conversion of a second cavity into a solid round focus. (3) Relaxation of a third cavity without any resultant healing.

P. Blasucci (*Minerva med.*, 1938, 29, 493) gives the following statistics of seventy cases of urethral stricture. The ages ranged from 7, in a boy in whom the stricture was due to trauma, to 81, in a syphilitic man suffering from an enlarged prostate. The average age was 53. Fifty-five patients gave a history of gonorrhoea, which in the earliest case had been contracted at the age of 13. Trauma was responsible for 10 per cent. In the remaining 10 per cent, the aetiology was doubtful. Fourteen showed clinical or laboratory evidence of syphilis. Nineteen gave a history of the exact age at which the first symptoms of stricture appeared, which ranged from 17 to 80 years and averaged thirty-eight years after the primary lesion. In eighteen patients it was possible to determine the interval between the first attack of gonorrhoea and the onset of disturbances of micturition. In three patients the interval was a few months, but in the majority it was much longer, being as much as sixty years in one case. As regards symptoms, 25 per cent. had complete retention and 25 per cent. had more or less difficulty in micturition. In 40 per cent. the chief symptom was painful micturition. Pyuria was found in fifty-seven (81 per cent.), haematuria in twelve, periurethral abscesses in fourteen, and periurethral fistulae in twelve; 36 per cent. were treated by gradual dilatation, 37 per cent. by internal or external urethrotomy, and the rest by suprapubic cystostomy, resection of the stenosed part of the bulbous urethra, or plastic operations.

Clinical Memoranda

Spontaneous Pneumothorax as a Complication of Artificial Pneumothorax

(WITH SPECIAL PLATE)

Numerous cases of spontaneous pneumothorax as a complication of artificial pneumothorax have been reported in the literature, but I have not found reference to any such case with the interesting features of the one here described. It is relatively common for spontaneous pneumothorax to develop on the same side as that on which the artificial pneumothorax has been induced, but in this case spontaneous pneumothorax occurred on the contralateral side.

CASE REPORT

A man aged 40 was admitted to Stobhill Hospital in April, 1933, suffering from pulmonary tuberculosis. The lesion, although active, was confined entirely to the upper lobe of the right lung. The case being a suitable one for collapse therapy, an artificial pneumothorax was induced in July, 1933 (Plate, Fig. 1). After this the patient's general condition improved greatly and he put on weight. His sputum remained negative throughout. He was discharged in October, 1933, and attended a clinic for air replacement and supervision until 1937.

On September 8, 1937, the patient, while sitting in a tramcar, was suddenly seized with a feeling of tightness of the chest and shortness of breath. He suffered great discomfort, but was able to make his way to the pneumothorax clinic, where he was examined.

He was admitted to Stobhill Hospital immediately, and was radiographed (Fig. 2). This film showed complete fibrosis and collapse of the right lung (the one in which the pneumothorax had been induced in 1933); and on the left side, which in 1933 had shown no disease, a spontaneous pneumothorax was now present. Despite the apparent seriousness of his condition as revealed by the film, the patient appeared perfectly well, showing no evidence of dyspnoea or cyanosis so long as he did not exert himself. He remained thus for his first seven days in hospital, but on September 15 he became breathless, and five minutes later was semicomatose and livid. Oxygen administered by nasal catheter was of little help, and an injection of adrenaline had no effect in relieving his symptoms. It was surmised that the pressure of air in the pleural cavity had risen sufficiently to cause the left lung to collapse almost completely. A needle attached to a manometer was inserted through the chest wall, and the air in the pleural cavity was found to be under considerable pressure. 2,000 c.cm. of air was aspirated in order to bring about a negative pressure and so allow the lung to re-expand. The patient was treated for shock, and in fifteen minutes he was quite well again.

Four hours later the patient had a similar attack of breathlessness and again collapsed. Another 2,000 c.cm. of air was withdrawn, and again the patient recovered within a few minutes. It had now become obvious that the pneumothorax was of the valvular type, allowing air to pass into the pleural cavity but not allowing it to escape, and it was only to be expected that the attacks of breathlessness would come on every few hours, whenever the pressure in the pleural cavity rose high enough. An attempt was therefore made to re-expand the right lung, which had been collapsed since 1933, in order, if possible, to give the patient some reserve lung tissue on which to work until the hole in the pleural cavity had healed. As was to be expected, the discomfort caused after the withdrawing of 300 c.cm. of air was such that the attempt had to be abandoned.

The pressure in the pleural cavity again began to rise, and in order to avoid the possibility of another collapse a hypo-

dermic needle was inserted through the chest wall. This had the effect of keeping the air pressure in the pleural cavity at the same level as that of the atmospheric air.

The patient remained well until September 17, when the needle became blocked and he collapsed again. After this he had no further breathless attacks, and the hypodermic needle was removed. He has remained perfectly well since. A radiograph recently taken shows that the left lung has re-expanded completely, and, incidentally, that an effusion has developed on the right side.

COMMENTARY

In the case described the cause of the spontaneous pneumothorax is not quite clear. It may be one of two things. First, it may be tuberculous in origin, due to a spread of the disease to the presumably healthy lung. Of this there is no evidence on x-ray examination, but the lesion at present may be very small. Secondly, it is possible that compensatory emphysema has developed on the left side, and that as a result of rupture of a bulla spontaneous pneumothorax has occurred.

Whatever the aetiology of the condition the treatment is the same. It is seldom that a case of bilateral collapse of this type is met with, but when it does occur the case is an emergency and requires immediate treatment.

The first point is to relieve the intrathoracic pressure. This is easily done if a pneumothorax refill apparatus is at hand, by using it to withdraw air. At the same time a knowledge of the intrathoracic pressure is obtained from the manometer on the apparatus. If, however, the apparatus is not available an alternative is to insert a needle into the chest and allow the intrathoracic pressure to fall to the level of the atmospheric air. This method can be further improved by attaching a piece of rubber tubing to the needle and leading the other end to a basin of antiseptic solution. The end of the tube is below the fluid level, and therefore allows air to escape but none to flow back into the chest. Sometimes it is necessary to keep up a system of continuous extraction, and for this an excellent method has been suggested by Boland (1934), in which he uses a Sprengel's pump to overcome the difficulty.

The majority of these patients die, but with energetic treatment an occasional life can be saved.

G. LAING BROWN, M.B., Ch.B.,
Medical Officer, Stobhill
Hospital, Glasgow.

Reinfection in Diphtheria

The case reported below is instructive for the following reasons: (1) It appears that it is possible for a patient admitted to a ward with diphtheria to become reinfected during convalescence with a different strain of *C. diphtheriae*. (2) The administration of diphtheria antitoxin in this case either retarded the development of the patient's own active immunity or, if active immunity had been developed, it was only selective for the intermediate strain and did not prevent a second infection of the gravis type. (3) It further raises the question whether patients suffering from diphtheria should be segregated according to their particular strains of infection.

CASE REPORT

In February, 1937, a child aged 3 was admitted to the City Infectious Diseases Hospital, Hull, with a history of sore throat, headache, and vomiting for three days. Both tonsils were covered with recent thin membrane, and there was slight adenitis and peri-adenitis of the associated cervical

glands. The condition was classified clinically as severe faucial diphtheria, and 8,000 units of diphtheria antitoxin were given intramuscularly and 8,000 units intravenously. A throat swab taken on admission yielded a good growth of *C. diphtheriae*, which on isolation in pure culture proved to be of intermediate type.

The membrane completely disappeared and the adenitis subsided in three days. Proteinuria was present from the tenth to the seventeenth day of disease. During the first fortnight there was some toxic change in the myocardium as evidenced by the pronounced weakening of the first sound in the mitral area, which persisted with decreasing obviousness into the fifth week. The patient continued to make normal satisfactory progress, and on the thirty-ninth day was allowed to sit up in bed.

On the forty-fifth day, when beginning convalescence, the child's temperature suddenly rose to 101.5° F. and the pulse rate to 136. A patch of membrane was visible on the right tonsil, and 8,000 units of diphtheria antitoxin were given intramuscularly in desensitizing doses. The following day a small patch of membrane appeared on the left tonsil. A throat swab showed the infecting organism to be *C. diphtheriae* again, but this time of the gravis type. There was no further growth of the membrane, and in two days the throat was clean.

There were no subsequent complications and the patient was discharged on the seventy-fifth day.

I am grateful to Dr. H. Mason-Leete, medical superintendent, for his permission to publish this case.

PHILIP SCIENCE, M.D.,
Late Resident Medical Officer, City
Infectious Diseases Hospital, Hull.

Sea-sickness as a Possible Aetiological Factor in Volvulus of the Small Intestine

This case is of interest because of the association of severe sea-sickness with the occurrence of the volvulus, and also because of the difficulties of diagnosis in such a condition.

CASE REPORT

The patient was a healthy Swiss girl, aged 18, who had had no previous ill-health. Thirty-six hours after a very rough Channel crossing, during which she was violently sea-sick, she complained several times of intermittent colicky pains across the upper abdomen; there was nausea but no vomiting. Her symptoms were relieved by fasting, but returned when she again took food.

On admission to hospital as a possible case of appendicitis, the patient was in some abdominal discomfort; her temperature was 98° F., the pulse 68, and respirations 20. The abdomen was tender in the right and left hypochondria. No abnormality was detected in the chest, and the urine was clear. An accurate diagnosis could not be made, so she was treated on expectant lines, and her symptoms were relieved by fluid diet and local applications. However, when the diet was increased the acute pain returned.

As the patient was in acute abdominal pain on the fourth day following her admission a laparotomy was decided upon, though the pulse and temperature were still normal. At operation a volvulus of the mesentery involving the first few feet of the jejunum was found and relieved. The affected gut was congested and distended. No exciting cause of any kind was observed. The patient made a good recovery, with no recurrence of symptoms.

I can find no reference in the literature to volvulus following sea-sickness, but I feel sure that in this case the latter was an aetiological factor.

Resident Surgeon,
Southlands Hospital, Shorham-by-Sea.

Reviews

PSYCHOLOGICAL ASPECTS OF DISEASE

The Emotional Factor in Visceral Disease. By H. G. McGregor, M.D., M.R.C.P. Foreword by R. D. Gillespie, M.D., F.R.C.P. (Pp. 198. 8s. 6d. net.) London: H. Milford, Oxford University Press, 1938.

Towards the end of his life William Harvey wrote to a young medical man that though his own days as an explorer were over, it was a pleasure to welcome him as a participator in that enterprise. In like spirit elder members of the profession should welcome Dr. H. G. McGregor's work on *The Emotional Factor in Visceral Disease*, for it is one of the most encouraging signs in post-war medicine that many of the younger generation should have so speedily acquired wisdom concerning the psychological aspects of disease. Doubtless this is in part due to their freedom from the handicap of a rigid materialistic training, but it is also due to their own open-minded questioning of all things.

The author quotes Mohr as saying, "There is no such thing as a purely psychic illness or a purely physical one, but only a living event taking place in a living body"; which might well serve as a text for his own book. At the outset he reminds us, as did Starling, that the physiologists take care to exclude as far as possible any complicating factors from interfering with their mechanistic and chemical experiments. For their own purposes this is of course justifiable, but it obviously prevents their results from being applicable to the explanation of all the phenomena of disease. The newer conception of the influence of emotions in producing symptoms is, as he says, "of particular value in unifying the phenomena of human life. . . . Psychology and introspection study life from within; physiology and pathology from without. Each is complementary to the other . . . each is indispensable to a complete picture." This helpful introduction is followed by a lucid statement of the physiology of the expression of the emotions, in which stress is laid on the fact that man meets the altered requirements of his present state of civilization not with new organs but with organs of the same type as both his savage fellows and the lower animals. The phenomena which accompany emotion are the same as those which accompany physical exertion in self-defence or escape. The patient cannot be expected to realize this, especially as the cause of the emotion has so often been banished from the conscious memory. Hence a fear born of the unknown.

These principles are then applied to a study of functional disorders of the digestive, respiratory, and cardiovascular systems, and we may remark in passing that the only omission we detected was any reference to over-breathing tetany, a condition which seems to be of increasing frequency in nervous women. Throughout great stress is laid on the importance of a full history. A distinguished Viennese physician once said to his students, "Don't believe what the patient tells you; it isn't true." Whereas the fact is that even if what the patient tells you is demonstrably untrue about the disease, it can tell you a great deal about the patient who has that disease.

As Dr. McGregor points out, the emotional episodes that precipitate illness fall into two groups: (1) present emotional conflicts in conscious life, and (2) deeply hidden unconscious conflicts and complexes. Whereas the second group may call for the services of a psychologist, the first and larger group can be handled adequately by any

medical man who has the requisite sympathy and insight. For even in this group the sufferer has never associated his symptoms with his conflicts. Simply to explain how the former result from the latter is more than half the battle. Cases are quoted copiously in support of this thesis. The interactions between endocrines and emotional states are then discussed, leading to an admirable exposition of the autonomic nervous system in relation to the foregoing. A practical discussion on diagnosis and treatment brings to a close a book which all can study with profit, and which is invaluable to the beginner who is faced on entering practice with problems to which his ordinary textbooks of medicine provide no clue.

ANAESTHESIA AND ANALGESIA

Modern Anaesthetic Practice. Edited by Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D., F.R.C.P., and Alan Moncrieff, M.D., F.R.C.P. (Pp. 231; 6 figures. 10s. 6d. net.) London: Eyre and Spottiswoode, 1938.

Gas and Air Analgesia. By R. J. Minnitt, M.D., D.A. (Pp. 84; 12 figures. 3s.) London: Baillière, Tindall and Cox, 1938.

The object of *Modern Anaesthetic Practice* is to provide a practical manual suitable for the general practitioner in his everyday work. It consists of a series of articles by different authors, some of which have already appeared in the *Practitioner* and have been revised, while the remainder have been specially contributed for this volume. The editors have, with the aid of a masterly introduction from the pen of Dr. Blomfield, successfully overcome the lack of cohesion frequently observed in works of this nature, but evidence of multi-authorship can be detected, and it is disconcerting to find di-ethyl ether indexed apart from ether, and divinyl ether apart from vinesthene. Such great progress has been made in anaesthesia during the past decade, both in the introduction of new agents and in the development of advanced methods, that it is difficult for those not intimately concerned with the subject to keep abreast of modern technique. A book, therefore, which is written by experts, which surveys the whole field of modern anaesthesia, and which is essentially practical in its outlook is to be welcomed. Many modern anaesthetic procedures can only be learned by actual experience and are beyond the range of the general practitioner, but from this book the reader will obtain the maximum amount of information that it is possible to convey by print. In particular, the chapters on basal anaesthesia, spinal anaesthesia, and nitrous oxide contain a wealth of detail and much practical advice, while the chapter on endotracheal anaesthesia makes the insertion of an endotracheal tube seem ridiculously easy. There is a detailed account of the methods employed to secure anaesthesia and analgesia in midwifery, including also a description of the various types of apparatus employed for this purpose, and the chapters on anaesthesia in dentistry, local anaesthesia, and volatile anaesthetics contain much of value for those in general practice. The theoretical aspects of the subject are ably discussed and space is found for a consideration of the, unfortunately, little-appreciated risks of explosion in anaesthesia. Perhaps the most generally useful sections of the book, however, are those concerned with post-operative care and with anaesthesia in the child, both of which fall frequently within the domain of the family doctor, and may be a source of not inconsiderable anxiety. Many will turn for guidance to this book, which is well printed, produced, and arranged.

The profession is indebted to Dr. R. J. Minnitt for introducing and developing the nitrous-oxide-air technique

for securing obstetrical analgesia. In *Gas and Air Analgesia*, which is addressed primarily to midwives, he details the history of the method, describes the construction and use of the various forms of apparatus employed, and gives clear and concise directions for administration in both normal and abnormal cases. There are also chapters on the use of gas and air in minor surgery, and upon recent legislative developments. The appendices, which occupy nearly one-third of the book, contain research notes and the original communications on the subject. Not even the excellent illustrations can reverse the opinion that the historical details could advantageously have been condensed and the space thereby gained devoted to a fuller consideration of the practical aspects of the method.

A TEXTBOOK OF MEDICINE

The Fundamentals of Internal Medicine. By W. M. Yater, A.B., M.D., M.S. (Pp. 1,021; 255 illustrations. 35s.) New York and London: D. Appleton-Century Company. 1938.

This new work by the professor of medicine in the University of Georgetown aims at presenting "the minimal amount of knowledge of clinical medicine a medical student or general practitioner should have at his fingertips." But it should be at once added, to allay any anxiety that might possibly be aroused by the word "minimal," that the standard is not low. The student is advised to supplement, when he enters the wards, his knowledge by larger textbooks, systems, encyclopaedias, and monographs such as are recommended at the end of the twenty-one sections of this volume. Like other authors of textbooks Professor Yater has found it advisable to call in the help of colleagues for special departmental contributions, such as diseases of the nervous system, mental disorders, dermatology, ophthalmology, otology, and endocrinology. He has written ten of the most important sections, such as those on the cardiovascular, renal, haematological, respiratory, and digestive systems, metabolism, allergy, and diet. Further, he has collaborated with one of his eleven contributors in three other articles.

The text is clear, practical, and well arranged, and there are useful tables of classification; differential diagnosis receives special attention, and illustrations are supplied from wide sources and generously.

SURGICAL ANATOMY OF HEAD AND NECK

Surgical Anatomy of the Head and Neck. By John Finch Barnhill, M.D., F.A.C.S., LL.D. Introduction by Paul S. McKibben. (Pp. 921; 431 figures, with many in colour. 90s.) London: Baillière, Tindall and Cox.

This large, heavy, and rather unwieldy volume on the surgical anatomy of the head and neck justifies its dimensions by the size and clarity of the print, which make reading inviting. Most of the illustrations, however, are not artistic and many are crude. This is in part explained by the fact that the author is himself responsible for them, and they are of the blackboard kind made during a lecture. The author has practised as an oto-laryngologist for a long period of time while teaching the surgical anatomy of the subject, and this aspect of surgical anatomy is naturally uppermost. In commenting on haemorrhage from the superior longitudinal sinus he states that this is always troublesome, dangerous, and sometimes fatal, since it is impossible to ligate the sinus and it is difficult to pack it effectively; but surely the most effective way of dealing with a sinus haemorrhage is to apply a large muscle graft. American spelling frequently gives

a strange appearance to well-known words; thus we read on page 423 that the optic nerves dicussate, but duramater spelt as one word is new to us. A literary flavour is given to the work by odd verses scattered throughout, particularly in relation to plates; some of this is the author's own composition, other is borrowed, such as the lines of Oliver Wendell Holmes which appear under a plate of the base of the brain (p. 420).

While there is much in this book that is valuable (it is interesting to read the author's account of the sacculus endolymphaticus), there is much that might with advantage be omitted, such as the plates that depict resection operations for epithelioma of the lip. It is doubtful whether any surgeon to-day is performing the resection shown, which belongs to the mutilating type of surgery practised before radiotherapy was available. In connexion with the mastoid the spine of Henle is mentioned and a triangle, but we looked in vain for the name of Macewen or any reference to Charles Ballance: it almost seems like referring to Bill Adams alone in an account of the Battle of Waterloo. This is a work that pleases and annoys the reviewer: pleases because it contains much of a rather striking character, clearly enunciated and authoritative, and annoys because mixed with this there is much that appears shoddy, ill considered, and hurriedly assembled or merely redundant.

INTESTINAL DYSPEPSIA

Intoxications et Carences Alimentaires. By Maurice Loeper. (Pp. 259; 4 figures. 60 fr.) Paris: Masson et Cie. 1938.

The organic diseases of the stomach and intestine—that is, those with a defined pathological lesion as a basis—are less common in practice than the so-called functional diseases, in which there is an indefinite or variable cause or foundation. Professor Loeper and his colleagues, who have produced an interesting and suggestive book on these functional disturbances of digestion, have been led by their researches to discard the notion of alimentary dyspepsia. Cytodiagnosis of stomach contents and the use of the gastroscope have demonstrated that in most of these cases there is an attenuated gastritis, shown in the desquamation of epithelium, erosion, congestion, and oedema of the mucous membrane. Similar conditions in the intestine may produce disturbances of secretion and absorption of food during digestion. It has long been recognized that these troubles may be provoked by foods such as irritating condiments, rich and sharp sauces. In addition there may be in certain persons a congenital idiosyncrasy towards fats. But it is especially towards proteins that a susceptibility occurs, some foods carrying toxic bases already formed, some in which during the process of digestion histamine and tyramine may be formed. In about 80 per cent. of the cases the cause of toxicity is histamine, and as well as the local effects there are those which are commonly regarded as anaphylaxis, intolerance, allergy, or hypersensitivity. The bacteria of the digestive tract also contribute; some may be of proved pathogenicity, such as the salmonella group; others, though saprophytes, may produce toxins by acting on the food residues. At other times the bacteria may break through the intestinal barrier to become generalized or to infect the urinary tract during excretion. Thus general symptoms may arise, those of intestinal hypersensitivity, from affection of the blood, the vascular and nervous systems, and the skin. The digestive symptoms may not be severe; flatulence appears to be the most usual, and this is often increased by the simultaneous changes in the liver, which

diminish its detoxicating effect as well as slow the portal circulation.

Though most diets in ordinary life are adequate in food constituents and vitamin content, two factors may contribute to a state of chronic vitamin lack: the poor appetite of sufferers from intestinal dyspepsia and the insufficient absorption and storage, particularly of vitamin C, through accompanying disease of the liver. In these states, too, there appears to be an alteration of the metabolism of calcium and sodium. These various problems are dealt with in an illuminating way, and the diagnosis is attempted not only between these dyspeptic states and organic digestive disease, but also between them and neurosis—a state of hyperaesthesia which may be grafted upon the dyspepsia. Professor Loeper trusts an intradermal reaction with well-diluted (twenty times) milk rather than very dilute (1:100,000) solutions of histamine in the specific diagnosis. In treatment simplicity of diet is essential, correction of deficiency or excess of digestive juices, absorbents, and the use of injections of diluted milk intradermally for desensitization.

Notes on Books

Education for Marriage, by Mrs. ESTELLE COLE (Duckworth and Co., 3s. 6d.) comprises six chapters founded on talks given to classes of girls of varied type with the hope of dispelling that ignorance which is at the bottom of much marital disharmony. The first, on the parents' part in the training of children in sex matters, is perhaps the best. Rather an alarming amount of pathology creeps into the later chapters, though they contain much good sense and advice, especially in that on the honeymoon. That on the climacteric, male and female, looks very far ahead. Dr. Cole is more of a psychologist than a clinician. The section on birth control is erroneous and not up to date. Not everyone would agree that an engaged couple, if "ignorant of the vital facts of life, should seek information, not from the family doctor, but from a medical psychologist"; that coitus interruptus should be avoided "at all costs"; that impotence is "very common"; nor that "floodings" at the menopause "necessitate prolonged rest in bed." The book would be useful as specimen talks to teachers who wish to share in the good work of dispelling dangerous ignorance rather than for perusal by young people themselves.

A new edition has now appeared from the Oxford University Press (12s. 6d.) of *Oxygen and Carbon Dioxide Therapy*, by Drs. ARGYLL CAMPBELL and E. P. POULTON, which was very favourably reviewed in these columns on its first appearance four years ago. An addendum dealing with the oxygen tent and nasal catheter is now incorporated in the volume; most of this appeared as an article by Drs. Poulton and T. W. Adams in the *British Medical Journal* of March 21, 1936. We agree with Sir Leonard Hill when he says in the foreword that "the authors of this book have rendered valuable service in putting together in concise form a mass of information scattered in scientific literature, and combining this abstract with the results of their own extensive research and clinical observation, thus making the whole subject of oxygen therapy available to the medical practitioner."

On the Danger List, by Dr. SÁNDOR PUDER (Constable and Co., 7s. 6d.) is an account by a doctor of his experiences in undergoing three operations. He was singularly unfortunate in suffering twice from a perforated appendix and in having to submit to a third operation for removal of the appendix and repair of a scar hernia. He was given ether for his first operation and developed post-anæsthetic pneumonia which very nearly killed him. His second operation was done under local infiltration anaesthesia,

and he is by no means enthusiastic about this from the patient's point of view. His third operation was done under spinal anaesthesia, and he seems to have been unfortunate here, too, in the degree and persistence of headache and the other discomforts from which he suffered afterwards, though he preferred this to either of his previous anaesthetics. Being by nature introspective, he has written an account of his illness and operations as seen from the patient's point of view, which should be read by every doctor. A foreword has been written by "Anthony Weymouth." We do not share his confidence in the effect this book would produce on the layman. We fear that it would frighten the average patient, man or woman, so badly that he would probably refuse to submit to any operation, even of the most urgent description. But by way of reassurance, we may say that the author was unfortunate in his premedication; more attention is paid to it in this country.

Under the title *Dental Disease: Its Chemical Causation and Cure* R. G. TORRENS puts forward his views on the aetiology and treatment of dental disease, and not only of dental disease but of most of the diseases to which the body is heir—including the common cold. "All disease results from a deficiency or condensation of electrical energy," and "health depends on a freely available interchange of atomic energy in the body"; the "electronic" state of the blood is to be determined (the author considers the pH of the saliva mirrors the state of the blood and estimates this by a colour test) and the patient treated accordingly. Much is promised if the author's methods be followed—for example, "by estimating the electronic upsets, and correcting these as a pre-operative measure, dentistry and medicine would banish difficulties in anaesthetic cases and render after-pain and surgical shock a thing of the past." For our part we are unable to follow the author either in his electrochemical introduction—which we think might with advantage be greatly shortened—or in his clinical descriptions. If, as the author seems to hope, a new era in medicine is opening, it needs a clearer exposition. The book is published by Henry Kimpton at 10s. 6d.

Mis-mated: The Principles of Incompatibility of Temperaments in Marriage and Family Life, by JOHN F. PETERS, is published by John Bale Sons and Curnow at 7s. 6d. The author has convinced himself that a person's attitude to life is determined by his relationship with other children, usually brothers and sisters, but sometimes close neighbours during his infancy—that is to say, that extroversion and introversion are conditioned responses. He further maintains that these varied conditionings determine compatibilities and incompatibilities in adult life, and that the study of the data presented in this book, which are the result of many years' study and investigations of a large number of both living persons and historical personages, would be of value in guiding those about to marry. How far the theories here set out will convince the reader may perhaps be determined by his own infantile conditioning. Whether the process of marrying and giving in marriage will be much influenced by this book we take leave to doubt.

Dr. G. E. BEAUMONT has produced a booklet, *Diets for Diabetes Arranged in Menu Form* (J. and A. Churchill, 2s.), containing sample diabetic diets used at the Middlesex Hospital. The examples are mostly of very low carbohydrate, high fat diets, and the diet tables old-fashioned in their arrangement. Surely to state that a certain meal contains exactly carbohydrate 6.6 grammes, protein 22.5 grammes, and 22.05 grammes of fat is too elaborate and hard to believe.

A copy of the Collected Papers from the Middlesex Hospital Medical School published during 1937-8 has been received from the Cancer and General Research Committee of the hospital, and can be consulted in the Library of the British Medical Association.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 17 1938

THE NEXT "BRITISH PHARMACOPOEIA"

Preparations are going forward actively for the publication of the next edition of the *British Pharmacopoeia*, which is due in 1941. It will be the seventh of the series. The first was published in 1864, the second in 1867; then came a long interval before the third was published in 1885. The fourth issue appeared in 1898, the fifth in 1914, and the current one dates from 1932. The *British Pharmacopoeia* can never be entirely abreast of current practice. Probably many users of the volume, seeing it for the first time, are surprised at its comparative slowness, and at the absence of many commonly prescribed preparations. As it is properly regarded as the official authority on drugs, the question always arises whether the absence of a monograph on a particular preparation is to be interpreted as a criticism of the trustworthiness of that preparation. Those responsible for the *British Pharmacopoeia* could never, of course, include preparations solely on the ground that they are widely used; that would be a dereliction of scientific duty. But they have been impressed by the representations made to them that it is desirable to include as many commonly prescribed preparations as possible. With the more frequent revisions now obtaining there is a better chance of avoiding the obsolete on the one hand and the unverified on the other, and of making the volume more nearly reflect current practice.

The reappointed Pharmacopoeia Commission, which took office in October, with Dr. A. P. Beddard again as its chairman, has given consideration to a list of new drugs of proved therapeutic activity. Among the drugs for which it is hoped to provide standards are a number of synthetic chemicals which have received general approval in medical practice and the manufacture of which is free from control by patents. Among these are mandelic acid, sulphanilamide, theophylline with ethylene diamine, benzedrine, and urethane. In the group of serological and bacteriological products additional antitoxins and vaccines will be included. Certain members of the group of hormones, including protamine insulin with zinc and some of the sex hormones, have been chosen for description. When the last edition was pub-

lished in 1932 certain international standards were available, but research work on hormones was then in progress which promised compounds of greater therapeutic activity, and so the Pharmacopoeia Commission at that time decided to await developments. These promises have now been fulfilled, and it is thought that the science of endocrinology has advanced enough to justify the grant of authoritative recognition to a number of products in the hormone series. Since the last *Pharmacopoeia* a great deal of research has also taken place in vitamin therapy, and this will be reflected in monographs relating to that subject. Vitamin B₁ has recently been isolated as a crystalline substance for which an international standard of potency has been adopted, and this will appear in the new volume. In pursuit of its policy of including preparations frequently prescribed if these are of established value the Commission proposes to bring in a larger number of such preparations as emulsions, liniments, nebulae, ointments, suppositories, pills, and compressed tablets. The opinion has grown amongst manufacturers and retailers that commonly used tablets, simple or combined, should be of standard weight, form, and composition, and a number of assay processes for tablets are under consideration by a committee. The Swiss and other European *Pharmacopoeias* already give such preparations official recognition, and the French *Pharmacopoeia* contains a general monograph which describes how the tablets are to be made and prescribes certain tests. It is expected also that steps will be taken to provide methods for the determination of many simple galenicals.

Several committees, each with a member of the Commission as its chairman, have been appointed to deal with specific subjects; over 550 monographs have been completed, and views have been exchanged on a lengthy list of suggested additions, deletions, and other amendments. The Commission works in close collaboration with the United States Pharmacopoeia Committee of Revision and with the similar bodies in Continental countries; and all the proposed alterations are submitted to the appropriate authorities in India and in the Dominions and Colonies. In the work of selection valuable help has been rendered by the Medical Research Council, the Science Committee of the British Medical Association, the Pharmaceutical Society of Great Britain, and other medical and pharmaceutical societies at home and overseas. In addition to the researches undertaken in the Pharmacopoeia Laboratory, a large amount of voluntary experimental work by experts in the various branches of pharmacy and pharmacology has been carried out to ensure that the descriptions

and standards shall be accurate and in accord with advances in practice. The Commission makes grateful acknowledgment of all this co-operation as it proceeds towards the conclusion of its task.

IMMUNIZATION AGAINST TETANUS AND DIPHTHERIA

The method of prophylactic immunization with formol toxoid which has given such invaluable aid in the control of diphtheria is now being used for the prevention of tetanus in man. No one would, of course, question the great service which tetanus antitoxin has given and will continue to give in the prophylaxis of tetanus, but this method is not without certain drawbacks. The immunity conferred is transitory, particularly so in those who have received serum before, and in the case of wounds which are slow in healing tetanus may eventually supervene unless the injection of serum is repeated. Again, tetanus spores may lie dormant in the tissues long after the wound has healed and may subsequently germinate with the production of tetanus. Active immunization with formolized tetanus toxoid should, in theory, overcome these particular shortcomings; whether it will do so in practice we should not be long in finding out, since this method of tetanus prophylaxis is now in use in the French Army and has recently been made available for our own soldiers. Even should this procedure do all that is expected of it—and the work of Ramon and his associates in France and of Major Boyd in this country would seem to show that it will—it is obvious that the application will be limited to those individuals, such as soldiers, whose risk of contracting tetanus is of a high order. One gathers, however, from investigations during the last few years by Ramon and his colleagues in France that those who have not previously been actively immunized can still enjoy the advantages of this method in the event of their being exposed to the risk of tetanus. The procedure proposed for them is a combined passive and active immunization: what Ramon terms sero-vaccination. The method consists in the simultaneous injection of a single large dose of antitoxin and 1 c.cm. of formol toxoid, the injections being made at different sites, followed by a second injection of 2 c.cm. of toxoid on the fifteenth day and a further injection of 2 c.cm. three weeks later. One might have expected that the antibody injected would interfere with the production of active immunity, but experiments on animals¹ and on man² would seem to show that this is not so. And in a recent

paper by Ramon, Kourilsky, Richou, and Mme. Kourilsky³ the results of titration of antitoxin in the blood of a number of individuals submitted to a somewhat similar but more intensive course of immunization leave no doubt that active immunization can be carried out under cover of a passive immunity. The procedure is said to be unaccompanied by any serious reactions, and Saquépée and Jude⁴ report having used it in the French Army with eminently satisfactory results. It also appears that a similar method is available for immunization against diphtheria, and that such a procedure is being used in France to immunize children living in a heavily contaminated environment.

The latest application of this knowledge is to employ sero-vaccination as a therapeutic measure in tetanus and diphtheria. It is difficult to understand what possible advantage combined passive and active immunization could have over serum therapy in tetanus, unless it were that, should the patient recover, he would be the possessor of an active immunity against this disease, and so not require a prophylactic injection of serum when exposed to the risk of tetanus on a subsequent occasion. In the case of diphtheria it is argued that a fair percentage of individuals are left with no immunity as the result of an attack of this disease and that the employment of serum-toxoid therapy would obviate this. It is further suggested that the occurrence of paralysis is possibly due to the fact that the immunity conferred by the injection of antitoxin at the beginning of the disease passes off rapidly, and that injections of toxoid would ensure the appearance of actively produced antitoxin just when that introduced passively was falling below an effective concentration. The course of injections advocated by Ramon⁵ consists of 0.1 c.cm. toxoid followed twenty minutes later by 1,000 to 2,000 units of antitoxin per kilo of body weight; subsequently 1 c.cm., 2 c.cm., and 3 c.cm. of toxoid are injected at five-day intervals. It is stated that the reactions produced are not severe and do not increase in severity as immunization proceeds; in fact, if anything, the later doses of toxoid gave rise to less reaction than the earlier ones. Debré and Mallet⁶ treated fifteen children by this method; they were all mild cases and ran an uncomplicated course. Sohier and Jaulmes⁷ report observations on seven cases, only three of which, however, need be considered, since the other four were acute carriers, were Schick-negative, and also had an associated slight sore throat. These three patients recovered; one

developed slight paralysis of the palate. Darré and Lafaille⁸ treated thirty-three cases, four of which were classified as malignant, seven severe, and twenty of moderate severity; there was one case of laryngeal diphtheria and one with diphtheritic paralysis occurring one month after the onset of an attack of diphtheria. All these patients recovered. The twenty-three cases with moderate or severe attacks were uncomplicated by paralysis, while the four malignant cases, though developing paralysis of the palate, had no general paralysis or cardiac irregularity. All these authors were impressed by the absence of severe reactions to the toxoid injections, and in each group of patients investigated antitoxin titrations made on the patients' sera showed that an active immunity of varying degree had resulted from the injections of toxoid. Since so few cases have as yet been treated by this method it is impossible to pronounce on its merits or demerits.

THE ANGLO-EGYPTIAN SUDAN

The Anglo-Egyptian Sudan, being a condominium, is subject to the supervision and control of the Foreign Office, but in practice has been allowed great freedom in the development of its various services. The report of the Medical Department for 1937 is, as usual, the first of the overseas reports to reach this country. It is of especial interest as it gives an account of the growth, since the early years of this century, of the Sudan Medical Service. The Sudan lies between latitude 4° N. and 22° N. and covers an area of approximately one million square miles—arid desert in the north and tropical forest in the south. The population, which numbered under two millions in 1899, is now estimated at rather more than five and three-quarter millions. Administration is complicated by the fact that about one hundred languages and dialects are spoken in the country. The Nile and its tributaries are still the main thoroughfares, though some two thousand miles of railroad track have been built in the north and dry-season roads serve most parts of the south. The foundations of the medical service were laid by the R.A.M.C. in the days of military occupation, but since 1904 a civil medical service has been available. An excellent system of hospitals now serves all the populous areas, and dispensaries with native attendants in charge have brought European medicine within reasonable reach of practically all the people. The Medical Department early realized that the greatest contribution it could make to the welfare of the country was to train local medical and sanitary personnel, and the efforts that have been made in this direction are beyond praise. There are only forty-five British medical officers in the Sudan Medical Service, but so well have they done their work that malaria, relapsing fever, sleeping sickness, cerebrospinal fever, and small-

pox have been kept under control: in 1937 no fewer than 561,196 persons were vaccinated against smallpox. Probably the greatest achievement of the Service has been the prevention of bilharziasis and of serious outbreaks of acute malaria in the irrigated area of the Gezira, an area which is of vital economic importance to the Sudan and in which conditions are most favourable for the spread of epidemic disease. In Khartoum a small group of specialist officers have set themselves a high standard of professional attainment, to which the Kitchener School of Medicine and the graphic Museum of Hygiene bear ample testimony. The staff of the Staff Medical Research Laboratories, besides carrying out a large number of routine examinations and undertaking a great deal of teaching, have found time to make a number of special investigations into typhus fever, Weil's disease, and relapsing fever. One of the reasons for the rapid development of medical and sanitary work in the Sudan during the last twenty years is that the thirty-three British medical inspectors in the Service are really inspectors. They leave as much as possible of the hospital work to the Sudanese medical officers and spend a large part of their time in inspection and educational work in their districts. Another reason is undoubtedly the short tour of service. The general rule is nine months' duty, three months' leave. Anyone who is still unconvinced of the folly of expecting first-class service from Europeans doing tours of two and a half to three years in the Tropics should visit the Sudan. There is no other part of our tropical Empire where the staff are so much "on their toes."

ACUTE NEPHRITIS AND THE STREPTOCOCCUS

The very close relation between acute nephritis and infection by the haemolytic streptococcus is well known, and most cases of acute nephritis occur from one to three weeks after tonsillitis, otitis media, mastoiditis, or some other infection of the upper respiratory tract. Recently an attempt has been made to show more clearly the role of the streptococcus in these cases.¹ J. D. Lytle and his co-workers have used two standards: bacteriological examination, and estimation of the antistreptolysin titre. Antistreptolysin is the factor that inhibits the haemolytic activity of the streptococcus in culture. It is found that patients who have not had a recent infection by the haemolytic streptococcus normally show less than 100 units of antistreptolysin in their blood. After an infection the titre rises to over 125, and in many cases to figures of 1,000 or more. Most of the 116 consecutive unselected patients with glomerulo-nephritis examined gave a recent history of infection of the upper respiratory tract. In 71.5 per cent. there was bacteriological evidence of infection with the haemolytic streptococcus, but as many were not examined until a week or more after the initial infection this figure is probably on the low side: in 94 per cent. there was an antistreptolysin titre of over 125. This seems to prove beyond doubt the importance of the haemolytic streptococcus in the causation of acute nephritis. An attempt was also made to correlate the amount of antistreptolysin present with

⁸ *Bull. Mém. Soc. méd. Hôp. Paris*, 1938, 54, 1405.

¹ *J. clin. Invest.*, 1938, 17, 631.

the severity or duration of the nephritis. The result, however, was indefinite, as the antistreptolysin appears to vary with the severity of the initial infection and not with the severity of the nephritis, and it is a known clinical fact that cases with a severe initial infection are not necessarily the worst from the renal point of view. It may be of some significance, however, that five out of the eight cases which developed chronic nephritis had low maximum antistreptolysin values. The same authors² have also investigated by clinical and immunological studies the question whether nephritis that has once healed is liable to recur. Among a large number of cases followed up ten patients were found who, after recovery from acute nephritis due to streptococcal infection, subsequently had a further infection with the haemolytic streptococcus. Eight of the ten had no further attack of nephritis, but two developed acute haematuria during the second infection. In none of these cases did the condition become chronic. Only one of the ten patients had oedema at any time; none had hypertension. Most of them would therefore seem to have been of the focal type, though these authors do not appear to distinguish between focal and diffuse varieties of acute nephritis. It is encouraging to learn that patients with healed nephritis may undergo subsequent infections with little risk to the kidney. Nevertheless recurrent attacks of haematuria, each associated with an attack of tonsillitis, are not uncommon.

TESTING CANCER "CURES" IN THE LABORATORY

The evaluation of alleged "cures" for cancer by laboratory methods is a difficult and depressing task. Dr. Anna Goldfeder¹ has tested three supposed anti-cancer preparations—namely, Schmidt's vaccine, "ensol," and Jacob's hormone extract. Schmidt's vaccine is prepared from killed cultures of a protozoan-like organism which, according to the originator, can be isolated from all malignant tumours and cultivated in artificial media; Connell's preparation "ensol" has been commented on widely; the method of preparing Jacob's extract is a secret. These preparations were applied to tissue cultures of human tumours; they had no destructive action. They were injected into mice bearing transplanted tumours and did not prevent growth. Finally they were tested on human patients with cancer, but no inhibitory effect on the tumours was observed: a detailed report of these tests is deferred. Dr. Goldfeder concludes that the three products "cannot be considered as anti-cancer preparations," and few will disagree with her. Still, it is opportune to examine more closely the methods of test, for cancer "cures" are bound to crop up from time to time and a heavy responsibility rests on those who condemn or condone their use on human patients. The tissue-culture method registers a direct action of the agent under test upon tumour cells but has limitations. Tumour cells growing under artificial conditions are not necessarily as vulnerable as those growing in the body, and, although there are many ways

of killing tumour cells *in vitro*, it is of no avail to destroy them by something which destroys the normal cells of the body at the same time. In the tissue-culture method it is difficult to arrange the essential control tests with normal tissues to demonstrate that an action upon tumour cells is specific and selective. Destruction of tumour cells *in vitro* is not, therefore, proof of therapeutic usefulness. The failure to kill tumour cells under the same conditions is no more proof of therapeutic inactivity. It may well be that malignant tumours are more vulnerable to indirect than to direct attack, and tissue cultures cannot register an action which depends on the stimulation of tissue or humoral processes within the body. Transplanted tumours of animals are essentially cultures of tumour cells growing in foreign hosts. An agent with a direct and specific action on tumour cells should destroy transplanted tumours without harming the hosts, but the process of transplantation results in new relationships between tumour and host, so that transplanted tumours regress under the action of agents which do not affect spontaneous tumours directly or otherwise. Tests on tissue cultures and transplanted tumours may yield strong presumptive evidence, but they are not conclusive. Tests on spontaneous tumours of animals are hampered by the difficulty of accumulating enough tumours to yield results which withstand statistical analysis. The difficulty is overcome in part by using inbred strains of mice in which cancer develops with high and regular frequency or by using, instead of spontaneous tumours, tumours produced experimentally by carcinogenic agents. The final test of a "cure" is its effect on human cancer. The laboratory investigator, combining the methods which are available to him, can form an opinion whether this test is likely to be safe and profitable.

CARDIAZOL FOR SCHIZOPHRENIA

Although cardiazol was used later in the shock treatment of schizophrenia than insulin, it is so much easier to administer that it is rapidly becoming the more popular of the two. Facilities for the latter method require special administrative organization and a specially trained staff; for the former all that is necessary is a supply of the drug and an enthusiastic physician. According to Dr. Isabel Wilson,¹ whose monograph is noticed at p. 1272, Dussik and Sakel claim full remission with insulin treatment in 70 to 75 per cent. of early cases; and Meduna with cardiazol in 75 per cent. Küppers,² giving the results from forty-five German hospitals and clinics, states that insulin treatment produced 39 per cent. of recoveries in cases of less than a year's duration, and cardiazol 53 per cent. In both series about one-fifth of the patients failed to improve at all. The methods of selecting the cases are still insufficiently standardized for a reliable comparison of the two treatments to be made. There are difficulties and dangers with both. Those of insulin are usually

of acute onset and appear as an emergency during the actual treatment. Once countered they leave no permanent effect behind, though while they last there is a serious risk of death. Such emergencies may arise also in the course of cardiazol treatment. Dick and McAdam³ have reported four cases of auricular fibrillation or acute heart-block occurring shortly after the injection and persisting for a period ranging from hours to days. With cardiazol, however, more lasting damage may be done. The frequency of fractures produced in the cardiazol fit is well known to those engaged in this method of therapy. Dislocation of the shoulder and jaw is so common that it hardly causes comment. Dr. Pameijer,⁴ from the statistics of Dutch university clinics, stated that in 1,200 cases treated with cardiazol there were fifteen cases of fracture, most usually of the femur, and not infrequently bilateral. He also records seven cases of pulmonary abscess and "many cases of cardiac complications with two deaths." In all, there were four deaths in the 1,200 cardiazol cases as compared with six deaths in 700 insulin cases. So far as the mortality rate in treatment is concerned, cardiazol compares favourably with insulin. With cardiazol therapy there is, however, another risk to be faced which does not appear to be a matter of moment when insulin is used, and that is the risk of secondary dementia. Plattner⁵ has reported seven cases in which there was failure of memory after combined treatment with insulin and cardiazol, and attributes the dementia to the fits set up by the latter. Insulin alone did not produce this syndrome, except in one case in which there had been a series of epileptic fits. Cardiazol is now being given not only for schizophrenia but for other psychiatric syndromes. It has been employed with success, for instance, in depressive states, and particularly in the somewhat chronic melancholic psychoses of the involutional period has given the impression of rapidly cutting short the illness. Recovery from these states, however, takes place to a large extent without any specific therapy, and it is possible that the advantages of cutting short the illness may be outweighed by the production of some permanent mental impairment. Further investigation of this serious risk is urgently required.

WHAT ARE EXAMINATIONS FOR?

Reprinted, with a small amount of additional matter, from the *Year Book of Education*, under the title of "The Purposes of Examinations,"⁶ is a symposium with contributions by twenty-two university professors, readers, lecturers, and inspectors, with an introductory article or survey by Sir Philip Hartog, Director of the International Institute Examinations Enquiry. It is of great interest, and should be of real practical value not only to examiners but to teachers of all grades, to students, and to others concerned with education. The

three chapters of most interest to members of medical faculties, colleges, and schools are the introductory survey, and those dealing with the M.B., Ch.B. degrees of the University of Edinburgh by Professor T. J. Mackie, and the final examination for the M.B., B.S. degrees of the University of London by Professor F. R. Fraser; but many of the other chapters on specific examinations contain observations which have a definite relevance to the general subject or to tests of professional competence. It is obvious that examinations serve several purposes, and that even a single examination may properly serve more than one specific purpose; but it is of the utmost importance that those who conduct any examination should realize clearly the purpose or purposes which it should be made to serve. Sir Philip Hartog emphasizes their use as tests of utilizable skill as distinct from tests of mere knowledge or memory. Particularly is this the case with reference to those final technical examinations which admit to the exercise of a certain specific calling or profession. It is interesting to note the method of applying this test to the medically qualifying examinations both in Edinburgh and London, and, presumably, elsewhere. The minimum prescribed for a pass is 50 per cent., but the assignment of this percentage is not effected by a mere addition of marks; it is determined by the judgment of the examiners as to whether it would be safe to allow a particular candidate to practise his profession or not. The minimum standard for this purpose in the mind of the examiner is assessed at 50 per cent., and deviations above or below this level are marked accordingly. Even so, Professor Fraser points out that such an examination must be more than a test which determines the degree of utilizable skill. It should also show whether the candidate has sufficient knowledge and understanding to avoid actions that may have serious results. Among other purposes of examinations briefly noticed or discussed are the estimation of progress towards attainment, the testing of the efficiency of schools, of intelligence, and of "culture," and the placing of candidates in an order of merit or proficiency. Their imperfections for this last purpose are frankly acknowledged, except when the number of candidates is very small, or in the case of those candidates who are as a group the best or those who as a group are the worst amongst a large number. It is made clear, too, that where the exact purpose of an examination test is ill defined these imperfections will be the more marked and the less will the test be likely to yield consistent or reliable results. The effects—as distinct from the purposes—of examinations on the curriculum of schools and their good or bad influence on individual candidates are referred to; and it is interesting to note that, while Professor Fraser is not entirely satisfied with the London University examination, and even regards its standard as a qualifying examination as unnecessarily high, Professor Mackie says, with regard to the examinations of the University of Edinburgh, that "the general feeling among examiners is that they yield a satisfactory result in testing the candidates' fitness." In this connexion he refers to the article by Dr. W. G. Millar in the *British Medical Journal* of December 12, 1936, and correspondence in subsequent issues.

although the surgeon at the operation could demonstrate no tear or displacement of the cartilage. The bone-setter thinks he has replaced a cartilage; the surgeon thinks he has removed a normal cartilage. Yet both have cured their patient. What is the explanation? That both bone-setter and surgeon are wrong in their suppositions: the cartilage was not displaced, nor was it normal.

The semilunar cartilage intervenes between the tibia and femur; it allows the femur to roll and to rotate on its upper surface, while its lower surface is gliding backwards and forwards on the tibia. Excessive mobility of the semilunar cartilage on the tibia is checked by the attachment of the outer rim of the cartilage to the capsule of the joint, but the binding material is lax enough to allow the semilunar cartilage to glide freely on the upper surface of the tibia. If the trunk is twisted while the foot is in contact with the ground the femur may be forcibly rotated in on the tibia, and this rotation force will tear the binding material connecting the rim of the cartilage to the capsule—a condition we may term rotation sprain of the knee. When the torn connecting fibres have healed, the mobility of the semilunar cartilage may be impaired, and during normal movements the capsule is pulled upon, giving rise to pain. The condition is curable by stretching the scarred connecting fibres by moving the knee forcibly in every direction under anaesthesia. Surgical removal of the cartilage also cures the pain, but the less drastic treatment by manipulation is preferable. The majority of surgeons do not operate on a semilunar cartilage without evidence that the cartilage has been torn and displaced. Positive evidence is afforded by a history of locking of the joint succeeded by unlocking. If this evidence is not forthcoming it is wise to try first the effect of manipulation, and only to operate if manipulation fails to cure. In the young adult a torn cartilage is more frequent than a rotation sprain, and vice versa in patients over 40.

The Ankle

The injury that is commonly called a sprained ankle is truly a sprain of the subastragaloid joint caused by excessive inversion of the foot. It is unfortunately still the custom to treat sprains by rest, and as a consequence of this treatment many patients develop adhesions. The usual story is that ever since a sprain of the ankle some weeks or months previously the patient has had slight puffiness on the outer side of the ankle below the external malleolus, and gets pain after using the foot. Examination reveals tenderness above the front and tip of the external malleolus, and pain on inversion of the foot in plantar flexion; these two movements are also less in extent than on the uninjured side. Often the foot has been immobilized in plaster by the harassed doctor in his search for something with which to pacify the patient; pain, however, returns when the foot is used actively again after removal of the plaster. The condition can be cured by manipulation. Under anaesthesia (nitrous oxide is often sufficient) the foot is forcibly plantar-flexed and inverted in one movement. As soon as the patient recovers consciousness he is encouraged to exercise the foot in the direction that previously was painful. Skipping and hopping on tiptoe are excellent. A week's supervision by a masseuse completes the cure.

The Foot

Much misunderstanding about painful feet comes from the obsession—shared by patient and doctor—about the arches of the feet. The patient, believing that a fallen arch is the sole reason for pain in the foot, demands either from the doctor or from the instrument-maker a support

to restore his arch; and often the doctor weakly accedes to the request. It would be so much better if we all thought in terms of joint movement instead of arches. When confronted with a patient who complains of painful feet our line of reasoning should be, I think, as follows: Is the cause of the pain purely mechanical, due to the stress of weight-bearing or of walking? If so, can we do anything to diminish the stress? If one movement is painful manipulation will often cure. If the patient, when standing or walking, is using the extreme range of movement of any joint and so putting tension on ligaments we can often increase the range of movement by manipulation.

Foot supports have only three useful functions. They can, by making the bearing surface of the shoe fit the under surface of the foot, increase the weight-bearing area; and they can take pressure off any portion of the foot that is tender. Lastly, they can restrict the movement of a joint to its painless arc; rather than do this, however, it is often better to attempt by manipulation to restore a painless range of movement.

The supreme importance of the toes in walking is not sufficiently appreciated. Many cases of metatarsalgia—thought by the patient to be caused by a dropped anterior arch—arise because the toes are clawed—that is, flexed at the interphalangeal and extended at the metatarsophalangeal joints. These toes can often be straightened either gradually by the repeated manipulation of a masseuse, or rapidly by manipulation under anaesthesia.

The Neck

Pain referred to the suprascapular region and down the arm is frequently cured by a manipulation of the neck. Headache and earache may also be relieved if associated with painful movements of the neck. As with every other joint, an x-ray film should be taken before manipulation is decided upon; but osteo-arthritic tipping, particularly of the bodies of the fourth and fifth cervical vertebrae, is not a contraindication. Faradism and exercises should follow the manipulation.

Upper Part of Back

Many an obscure thoracic or abdominal pain disappears after manipulation of this region of the spine. Interthoracic and interabdominal lesions must first be eliminated.

Lower Part of Back

Sacro-iliac subluxation is a diagnosis often made to account for low backache. Whether the sacro-iliac joint ever does subluxate is doubtful; but there is no doubt that many patients labelled with this diagnosis are cured by manipulation. It seems probable that the clinical term "low backache" comprises several pathological entities. Unless there are definite contraindications manipulation should always be tried. It can do no harm, and even if it does no good it is of value in elucidating the diagnosis and as a guide to further treatment. The contraindications are: (1) X-ray evidence of bone disease; simple anomalies of structure are, however, of no importance. (2) Neuritis, evidenced by muscle wasting, nerve tenderness, and loss of ankle-jerk. (3) Total rigidity of the lumbar spine from spasm of the erector spinae muscles.

Causes of pain other than of skeletal origin should first be excluded before resorting to manipulation. Complete muscle relaxation is needed; intravenous pentothal gives this for certain, but cyanide is often insufficient. The use of an anaesthetic of short duration and with no after-effects has the advantage that active exercises can be started early.

BRITISH RADIOLOGICAL CONGRESS

CONTACT X-RAY THERAPY

The twelfth annual radiological congress under the auspices of the British Institute of Radiology was held at the Central Hall, Westminster, from December 7 to 9. In addition to a number of papers dealing with the applications of x rays to the arts and sciences (including the art or science of crime detection), there were two medical sessions, one devoted to therapy and the other to diagnosis. One of the two memorial lectures in association with the congress also had a medical subject. Associated with the congress was an exhibition of x-ray apparatus, to which over twenty firms contributed. A prominent feature was the apparatus for low-voltage contact therapy, which was the subject of one of the discussions. The congress was under the general presidency of Mr. W. E. Schall, the president of the Institute, but Dr. Maitland Beath and Dr. L. A. Rowden presided over the medical sessions.

Professor J. M. WOODBURN MORISON, in opening the discussion on low-voltage contact therapy, said that this was supposed by some not to be a new method. The tube was very much like the Lenard tube used in 1894, and thirty-five years ago radiologists were working with low voltages and getting results sometimes quite good. But no tube exactly like the tubes now to hand for Chaoul therapy had been available before to give radiation having a geometrical distribution in the tissues, imitating the distribution of the radium applicator and to some extent that of the radium "bomb." With this low-voltage contact or Chaoul therapy irradiation was so circumscribed that the healthy tissues around the lesion sustained no damage, for, after all, radiation was damaging, and all living tissue could be destroyed by it if it were applied in sufficient amount. It was, indeed, the special virtue of radium that with the gamma rays there was no selective action, but a purely geometrical distribution. By no means all cases were suitable for these methods. The field was limited at present, though as time went on it might be extended with the help of surgical intervention in the case of lesions less accessible. The real problem for the radiologist in the treatment of cancer was the accessibility or otherwise of the lesion. Surface lesions were accessible, and it was here—in cancer of the oral region, for example, or cancer of the cervix—that radium had been most successful.

Comparison of X-ray and Radium Treatment

The Chaoul apparatus, Professor Morison went on, could deliver anything from 100 to 200 *r* units a minute, whereas with radium the rate of irradiation was very much smaller (a later speaker said that 1 mg. of radium at 1 cm. gave 9 *r* an hour). Consequently with the former method a larger number of cases could be dealt with in a given time. It was not a question of two or three hours' treatment daily, but of two or three minutes' treatment, for many of these cases. So far as the reaction to low-voltage x rays was concerned, this was very similar to that with radium for an equivalent dosage of *r* units. There was no more flexible apparatus than the Chaoul tube; it could be easily handled, and the rate of irradiation and distance from the tissue readily adjusted. So precise an instrument was it that he felt it should be installed in every x-ray department where research work was done. It was quite easy to treat superficial lesions and get excellent results, and with surgery of access it would be possible to tackle such conditions as bronchial and oesophageal carcinoma, for which radium was extensively used. Some cases of cancer of the rectum had been treated by this method at the Royal Cancer Hospital.

Among the superficial conditions the treatment was specially effective in rodent ulcer, and in such a condition as rodent ulcer near the inner canthus an even distribution of the radiation was secured by a wax filling composition. In one case of rodent ulcer the actual dose given by the Chaoul method was 5,700 *r* spread over twelve days, equivalent to treatment for two or three minutes a day. The scar formed was soft, pliable, and painless. As a rule, 400 *r* was the daily dose. Cases of large epithelioma of the lip and elsewhere had been successfully treated. Metastases should be treated by high-voltage x rays of 200 or 400 kV, but the primary lesion was best dealt with by low-voltage contact therapy. He showed a table of statistics of cases treated from 1935 to 1938 with low-voltage short distance or contact therapy, using the Chaoul apparatus. The cases numbered 500 (312 malignant and 188 non-malignant), the malignant cases including 102 cases of epithelioma, also 100 of cancer of the breast. A high percentage of successful results was recorded in the different categories. Of the eighty-two cases of rodent ulcer treated, 97 per cent. were alive and well, with no sign of recurrence.

Radium was very much in the public eye at present, said Professor Morison, and people had got an impression that it was a cure for cancer. But only a very small proportion of cases were suitable for radium treatment, and nothing was done with radium which could not be equally well accomplished by suitable x-ray applications. The economics of the question deserved some study. Even if, for the sake of argument, the radium "bomb" were a cure for every type of cancer—which was not true—a "bomb" could treat, perhaps, 200 cases a year, and about 140,000 cases, apparently, required treatment. So far as his knowledge went there were 90 grammes of radium available in this country.

Technique of Contact Therapy

Dr. J. STRUTHERS FULTON, who showed a colour cinematograph film of the technique of contact therapy, said that while low-voltage x rays had been successful in treatment for the past thirty years, the present technique had become possible only as a result of the development of shock-proof equipment. The chief advantage over radium was in the high dosage rate—a dose of 300 *r* per minute at 3 cm. distance enabled a large number of patients to be treated with the one plant. The treatment might be fractionated to a daily exposure of one to three minutes, though in the case of malignant lesions limited in extent it could be given in one single massive dose lasting not more than fifteen minutes. The elimination of stray radiation presented no problem, and the x-ray beam was accurately confined to the area under treatment. At the kilovoltages employed the characteristic rays of lead were not emitted, and therefore that substance might be used directly on the skin to define with accuracy irregular areas of treatment. In the case of certain lesions in the mouth and throat, where the implantation of radium presented technical difficulties, x rays might be used successfully, and by using focus skin distances up to 20 cm. correspondingly large areas could be treated.

The apparatus the working of which he described was installed at the Western Infirmary, Glasgow. The film he projected was designed partly to show the flexibility of the tissues treated after healing had taken place. The cases demonstrated included epitheliomas of the lip and other parts of the face. It had also been possible to use the method for localized tumours of the bladder.

Dr. G. J. VAN DER PLAATS of Utrecht spoke on the same method for the treatment of superficial cancer. The advantages of the method were soft radiation, short distance, and fractionized dose, though, of course, this last could be applied to other methods also. The object was to get a sufficient dose, say 3,000 *r*, at the base of the tumour, not troubling about what the skin received, but ensuring that as little radiation as possible penetrated the underlying healthy tissues. His usual technique was to employ a 2 cm. focal skin distance and a filter of

0.2 mm. aluminium. The very short treatment time enabled him to dispense with tube or applicator stands; he simply held the tube in his hands, with the cable across his shoulder. He had treated more than 100 tumours by this method with excellent results.

Radiology in the Diagnosis of Urinary Infections

Sir GIRLING BALL, who addressed the congress on this subject, began by lamenting that so often general practitioners, instead of sending cases of chronic urinary infection for examination, treated them for a long time with various drugs. He spoke principally of infections in which *B. coli* and its group were concerned. The persistence or recurrence of an infection with this organism indicated some lesion of the tract which predisposed to the condition. So far as lesions of the lower urinary tract were concerned, cystoscopy was the first method of examination. Usually more information could be given by cystoscopy than by radiography, but there were two exceptions—namely, those cases in which the cystoscope could not be passed into the bladder, and those in which there was diverticulitis of the bladder. In the case of lesions of the upper urinary tract, the surgeon could not get on at all without the help of the radiologist. He had operated on over 300 cases of stone in the kidney, and in only one of them was there no shadow shown in the x-ray picture.

With the help of numerous radiographs Sir Girling Ball indicated various pitfalls. He showed one case which had been diagnosed as calculus. The patient had a very mild type of urinary infection; the organism found was the *Staphylococcus albus*. The supposed stone turned out to be a small localized tuberculous focus in the kidney, giving a calcified area. If an attempt had been made to remove what was thought to be a stone the real disease would have been left behind, and the patient's condition would have become worse. He also stressed the importance of having a pyelogram of both kidneys in congenital hydronephrosis and in other conditions, and, further, the need in all cases of doubt as to the findings with the intravenous pyelogram of combining a retrograde pyelogram with it. Intravenous pyelography was a simple method which could be employed in any patient, but there were errors which came about if retrograde pyelography were not employed.

Dr. L. A. ROWDEN regretted that the practice of screen examination in renal cases was so rarely employed. Careful examination on the screen would reveal features and correct errors which were beyond the capability of the negative. For example, on the screen a differential diagnosis between a stone and a gland could be easily made. Dr. DUNCAN WHITE said that before intravenous pyelography a blood urea test should be made. If there was no active renal tissue to excrete uroselectan it was obviously of little use proceeding. Dr. G. VILVANDRÉ also demonstrated some aspects of renal radiology, showing cases of unusual distribution of calculi and of congenital abnormalities, as, for example, the patient with three or four ureters. He agreed that retrograde pyelography was essential in quite a fair proportion of cases. X-ray examination, after all, was only one of the examinations which were needed in the diagnosis of urinary and vesical disease.

"Stereo-radio-stratigraphy"

Dr. C. CHAUSSÉ of Paris discussed the application of the various methods, of which tomography is the best-known example, of radiographic analysis. He had invented a special stereo-radiographic table with a centring device, in which the central ray from the tube passed through a fixed point, and he showed how this could be used for obtaining stereoscopic images and also, with some adjustment, for obtaining the successive planes used in tomography. He showed a number of planigraphic

sections through the skull and through the auditory apparatus, and specially stressed the value of the method in otology. He also described for the second time in England (the first description having been given at the Section of Otology, Royal Society of Medicine, on November 4) an adaptation of the apparatus to the combined localization and extraction of radio-opaque bodies. This was done by means of what he called the luminous compass. The compass is made by two beams of light, one of them representing the central ray of the x-ray tube and the other so arranged as to be coincident with the first at the localization of the foreign body. The localizer is used on the actual operation table, and the surgeon in his dissection is guided by the beam. As the two luminous spots approach each other he knows that he is nearing the position of the foreign body, and when they meet, that his probe has actually reached it. The instrument, which embodies the principle of the theodolite, evoked much interest.

X-ray Diagnosis of Gastric Cancer

The twenty-first Silvanus Thompson memorial lecture was delivered by Dr. LEDOUX LEBARD of Paris, whose subject was "The X-ray Diagnosis of Gastric Cancer." Medical students were taught, he said, that gastric cancer was a disease of very short duration, and that continuous loss of appetite and weight were two cardinal symptoms; also that in the prolonged absence of pain the patient usually sought advice too late for operative surgery, and therefore early x-ray diagnosis was only now and then possible. These statements were not necessarily true. Gastric cancer showed great differences in duration. He recalled two cases, one of which was three years in evolving and the other nearly five. In regard to appetite and weight, he instanced one patient whose excellent appetite persisted until a week before radiographic examination revealed a hopeless condition. Malignancy of the ulcerous form was much more difficult to recognize than simple ulcer. Most of the characteristic x-ray features were only demonstrable on the film and not fluoroscopically. The development of these tumours was generally very slow. By a series of radiographs he indicated the changes of contour, more especially on the lesser curvature, which were pathologically significant. He stressed the ability of the x-ray picture to reveal quite small manifestations which were hardly detectable by any other method.

The other memorial lecture delivered in connexion with the congress was on the influence of x rays in pure and applied science, by Dr. G. SHEARER of the National Physical Laboratory. It is interesting in view of the collaboration of physics and medicine which the Institute represents that that lecture, in memory of a medical man, Sir James Mackenzie Davidson, should have been delivered by a physicist, and the other lecture, in memory of a physicist, Silvanus Thompson, should have been delivered by a medical man.

SHOCK TREATMENT OF SCHIZOPHRENIA

A report, prepared for the Board of Control by Dr. Isabel Wilson, on the new methods of treatment of schizophrenia has been issued.¹ It is a small and handy booklet that should be of considerable service to those engaged in these methods of treatment, and is of interest to psychiatrists in general. On the instructions of the Board of Control Drs. Rees Thomas and Wilson visited numerous treatment centres both on the Continent and in England, and

¹ Report on Cardiac Treatment and on the Present Application of Hypoglycaemic Shock Treatment in Schizophrenia. By W. Rees Thomas, M.D., F.R.C.P., D.P.M., Medical Senior Commissioner of the Board of Control, and Isabel G. H. Wilson, M.D., M.R.C.P., D.P.M., Medical Commissioner of the Board of Control. London: H.M. Stationery Office. 1s.

Dr. Wilson, in addition, has reviewed the greater part of the now exceedingly extensive literature on the subject. The report provides a useful compendium of the method of treatment with cardiazol, with insulin, and with combinations of the two methods; the staffing and other administrative arrangements required; the dangers and complications and contraindications to treatment; theories of the mechanism of improvement; and the results obtained hitherto. The literature reviewed includes 152 references, and the bibliography is of great value to any student of the subject. It is an eminently practical volume, and might well be used as a working handbook by superintendents and others desiring to start one or other of these new methods.

Although the report suffers from lack of personal experience in treatment of either author, the technical methods and other data are taken from authoritative sources and should be reliable. A greater weakness is the lack of any critical attitude in the evaluation of the work of different authors, which shows itself particularly in the discussion of the theories of the mechanism of improvement, many of which are highly speculative and fanciful. As a result of their investigations Drs. Rees Thomas and Wilson are obviously of the opinion that the application of these methods of treatment should proceed. They cautiously state as their conclusion that "results are encouraging, but the well-known difficulties of statistical evaluation have not been solved."

Reports of Societies

ILLEGAL OPERATIONS

A dinner-discussion took place at the meeting of the West London Medico-Chirurgical Society on December 2 on the subject of "Illegal Operations." Dr. MAURICE SHAW, president of the society, was in the chair.

Mr. CECIL BINNEY, barrister-at-law, said that of all illegal operations that for abortion was the only one which, medically speaking, was specifically forbidden by law. It would be, however, substantially true to say that all operations were illegal unless they were rendered necessary for medical reasons. Sterilization, for example, unless it was carried out for the health of the person concerned—if it ever was—was clearly illegal. To say that there was not likely to be a prosecution was irrelevant. One could easily imagine prosecutions should anyone set out to perform such operations as a commercial venture. But while operations for sterilization were illegal because they came within the words of the Offences against the Person Act, 1861, operations for abortion were more specifically forbidden, probably because the interests of a second person—namely, the unborn child—had to be considered. To bring to an end something that had already begun was in a different category from preventing something from beginning. Thus contraception was different from taking active steps to terminate the life of a child once it had begun. Although the law permitted a doctor to induce miscarriage if it was considered necessary to save the woman's life, it was more rigorous in this sphere than in that of other operations in which the interests only of the individual were concerned, because in abortion it was a commencing life which was destroyed. But it might be, following the recent trial of *Rex v. Bourne*, that the law was altering.

Changes in Thought and Practice

Mr. ALECK BOURNE excused himself from saying anything about the recent trial, a subject of which he was heartily tired. The ideas on this subject at present were governed by three main conditions. There was first the ecclesiastical view; canon law had contributed consider-

ably to civil law. Secondly, there was the effect which the widespread practice of abortion might have in a decline of population. Thirdly, there was the consideration of the physical dangers of the practice. Ancient Greek writers referred to a widespread practice of abortion, but made no mention of laws which prohibited it. In fact, Plato went so far as to advise abortion for all women who became pregnant after 40 and all whose husbands or paramours were over 45. In Roman times there were many references to the practice, but again none to penalties until, he thought, Cicero advocated punishment. But the idea of penalty was vague until the Christian era. The early Christians were a downtrodden people, amongst whom, as a relief from their present sufferings, the idea of the joys of the immortal life hereafter became paramount, and this led to emphasis on that moiety of man, the soul, which was destined to live after death. Thus it was easy to see how foeticide was held in particular abhorrence, because it meant the killing of that part of man which was endowed with the capacity for eternal enjoyment. As Christian ideals spread among Western peoples there went, together with the idea of the imperishability of the soul, the classification of an operation for abortion as a major crime. In the Middle Ages the laws against abortion were savage; the offence was punishable by death for both the woman and the abortionist. In the seventeenth and eighteenth centuries the subject entered upon a less barbarous phase, but he believed that nothing definite was codified until the Act of 1861.

To-day there was an increasing desire among women for this procedure. This was due partly to the decay of religious influence, partly to economic and domestic conditions, partly to the liberation of women from the shackles of reproductive life, and partly also to sheer lack of desire to produce children. Probably there was a greater prevalence of irregular sex relationships, and when these resulted in pregnancy there was a demand for its termination. Central Europe showed a different picture. There the desire was to have larger populations, partly for military purposes, partly to bring about population pressure and so justify aggressive policy.

The whole subject was one on which it was impossible to get hard-and-fast decisions, because it was governed by prejudice, ecclesiasticism, training, preconceived ideas. An imperative thing was to clean up the grossly illegal practice of abortion—practice by sharks who took from the pregnant woman not only her foetus but her purse. The practice of these people was utterly repulsive. But the law could not be left as it was. The law might well be widened so that the girl pregnant as the result of rape could be legally relieved of her pregnancy. Some method ought also to be devised whereby a doctor with one or perhaps two consultants, believing that the procedure would be for the ultimate benefit of the health of the prospective mother, might be allowed to perform it without the stigma which now inevitably attached to it. Actually it was very rarely necessary to induce abortion to save a patient's life. How many women were killed by the continuance of their pregnancy? But there were a very large number who were permanently incapacitated, whose health sank to a lower level, and who became less efficient as mothers to their previous family. He had no patience with canon law as applied to civil life. As the community were not all Christians ecclesiastical ideas should not be made civil law.

The Roman Catholic View

Dr. W. J. O'DONOVAN quoted from the summing-up of Mr. Justice Macnaghten in the *Bourne* case: "There are others [in the medical profession] who, for what are said to be religious reasons, object to the operation being performed at all in any circumstances." He drew attention to the scorn of the statement "are said to be." Surely that devastating comment need not have been made. The judge had gone on to say that in a case where the life of a woman could be saved by performing the operation, if

the doctor refused to perform it on the ground of some religious opinion and the woman died, "he would be in grave peril if he were brought before this court on a charge of manslaughter by negligence." This "menace" could be dismissed at once. If the patient were an informed Catholic woman no question would arise. If a Catholic doctor were in charge of a Protestant patient it was quite certain that he would explain such a matter to her responsible relations long before the crisis was reached, and it would be his duty, in justice to them, to indicate that it was customary among some members of the profession to carry out an operation to empty the womb in the attempt to save the mother's life. Whatever unconsidered enthusiasm this verdict might have evoked in the medical profession, they might be sure that the great body of silent and thoughtful people would feel that it left doctors with even less helpful guidance from the law and with less protection than they have formerly enjoyed. They would know that it conferred freedom on them, but added materially to the already heavy burden of their responsibility.

The rest of Dr. O'Donovan's remarks was a recapitulation of the fame and service of Catholic doctors in all ages. St. Luke was soaked in the tradition of Hippocrates, and the words of the Hippocratic oath were plain and without qualification: "I swear . . . nor will I aid a woman to procure abortion." "I do not envy a trial judge faced with a Christian doctor, Hippocrates, and St. Luke in the dock at the same time!"

The Principles of Eugenics

Dr. C. P. BLACKER reminded the meeting that the legal aspect of sterilization was discussed with great thoroughness by the Interdepartmental Committee between 1932 and 1934. The recommendations of that committee were influenced to a large extent by considerations arising from the problem of mental defect. There was no doubt as to the present illegality of this operation on the mental defective. With regard to those of sound mind he understood that the operation for voluntary sterilization was similar from a legal point of view to other operations of a non-therapeutic character, such as ritual circumcision, blood transfusion (in the case of the donor), and "face lifting." From the eugenic standpoint it was most desirable that any ambiguity in the law should be removed. The Offences against the Person Act, of course, was passed at a time when no one dreamed of such procedures; an operation for sterilization for eugenic purposes was performed for the first time in 1899, nearly forty years after that Act had been passed. Judged from the moral standpoint, there could be no doubt that an operation to terminate a pregnancy was more "shocking" than an operation to prevent pregnancy, for in the former case it was obvious that life which had already begun was being destroyed. On the other hand, judged from a biological point of view, there was little doubt that sterilization was the more drastic procedure, for the simple reason that to sterilize a person, the measure being to a large extent irreversible, was permanently to disqualify him for the function of reproduction. If they divested themselves of moral feelings towards these questions he thought it was clear that the sterilizing operation was from a biological point of view the more drastic. Hence it would be desirable to legalize, or rather to establish facilities for, the voluntary termination of pregnancy in such cases as would also be regarded as proper for sterilization, and it was in these respects that the question of illegal operations impinged upon the subject of eugenics.

Viscount DAWSON OF PENN said that it was true, as the opener of the discussion had remarked, that there must always be a lag between law and medicine, and rightly so, but the recent considerable change in public opinion had made the lag more manifest. He always thought it undesirable to regard change of thought in the community, perhaps involving a certain change of habit, as necessarily indicating some degeneration. He did not believe that the

changed ideas and habits of the people, although in some respects they might be mistaken, indicated any deterioration in the race. There were good reasons why many people desired to limit their families, but alongside that change it was undoubtedly true that children were better looked after to-day than they had ever been in the history of the country. So far as the medical profession was concerned he thought that any change of view might be due in part to that altered emphasis which was constantly being impressed upon the medical man whereby, instead of having as his one preoccupation the immediate problem of the sick person in front of him, he had now been instructed in the teaching of preventive medicine, and was always being told to look ahead, to anticipate, and to prevent. Half unconsciously there had come increasingly into the profession the idea of the good of the community, not the individual only. That in itself brought about an enormous change of thought, with a widening of horizons and an increased number of considerations to determine a given line of treatment.

Mr. V. B. GREEN-ARMYTAGE considered that those three elastic words which it was considered might be incorporated in the Act to give a ground of permission for legal abortion, "risk to health," were very dangerous. Who of them could define "risk to health"? It was an unscientific term. The unmarried mother was a person for whom one often felt a great deal of sympathy, and yet, after all, Leonardo da Vinci and Michelangelo were illegitimate children. What did it all boil down to? If the surgeon had no guilty intent, if he was perfectly honest in what he did, and if he took the precaution of calling another doctor into consultation, he would never in the present state of the law be convicted. There was no such thing as an illegal operation if there was no guilty intent.

Legal Views

One or two barristers present contributed to the remainder of the discussion. Mr. E. D. WETTON mentioned the desirability that any such operation should only be performed after two medical men had consulted. He thought also that words might be inserted in an Act of Parliament to indicate that the operation might be performed when it could be shown that the health of the mother would be permanently injured by having a child. Mr. G. K. ROSE (metropolitan police court magistrate) said that it astonished him to find that as the years passed by nothing was done actively to remove the stigma which attached to the illegitimate child.

Mr. GEOFFREY RAPHAEL said that his quarrel with Mr. Bourne was that his action had served only to emphasize the differences which existed between the law and the practice of medicine. It had done nothing to reconcile those views. So far from it being true that the law had been changed by that judgment, it had not been changed at all. Mr. Bourne was in respect of this case butting against an open door. Nobody would have ever dreamed of suggesting that Mr. Bourne in pursuance of his practice was committing a criminal offence. But of course when Mr. Bourne said, "This is what the Act says, and I propose to defy the Act and invite Scotland Yard to prosecute me," poor Scotland Yard could do nothing else. But that argument which availed Mr. Bourne, quite properly, at the Central Criminal Court might be advanced equally by professional abortionists, who did such incalculable harm.

At an extraordinary meeting of the Council of the Brighton and Sussex Medico-Chirurgical Society Mr. Douglas A. Crow was elected president to fill the vacancy caused by the death of Dr. J. G. Hayes. On November 3 Dr. H. G. McGregor read a paper entitled "Constitution." On December 1 Mr. D. A. Crow delivered his presidential address entitled "A Blind Man with a Lantern." At this meeting a collection for the B.M.A. Charities Fund produced more than £27.

Local News

ENGLAND AND WALES

Old Epsomians

The sixty-first annual dinner of the Old Epsomian Club was held on December 8, with Mr. S. J. Holford, L.D.S., in the chair. After the loyal toast had been honoured Mr. J. S. Colman proposed the health of the president in a brief speech in which he referred to the president's athletic achievements and to his eminence as a dental surgeon. In reply Mr. Holford expressed his appreciation at being elected president for the coming year, and entertained the company with reminiscences of his early days at the school. In responding to the toast "Epsomia," the head master, the Rev. A. C. Powell, said he would like to express the gratitude of the school to last year's president, Colonel Crawford, who had proved to be one of their greatest benefactors. He then gave some figures which indicated the increasing success of Epsom College in gaining scholarships at the senior universities. In sport the tradition of the school was also well maintained, especially in rugby. The head master concluded his speech by mentioning the admirable spirit shown by the school during the recent crisis. In welcoming the guests Sir Cosmo Parkinson said he would like to congratulate Dr. Robert Hutchison on his high position as President of the Royal College of Physicians, and he mentioned that Mrs. Hutchison was the only woman member of the College Council at Epsom. He coupled the toast with the names of Dr. Robert Hutchison and Mr. D. C. Barclay, chairman of the College Council. In a brief reply Dr. Hutchison said that it was a privilege for those guests who were not Old Epsomians to be admitted to such a "family gathering" as this evidently was. Epsom, he said, he had always associated with three things: salts, the race-course, and the school. Mr. D. C. Barclay, also responding for the guests, considered that old boys' clubs or societies were an important part of the life of a school.

Epsom College: St. Anne's Scholarships

The Council of Epsom College will shortly award several St. Anne's Scholarships for girls. Candidates must be fully 9 years of age and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected. Forms of application for these vacant scholarships can be obtained from the Secretary of Epsom College, 49, Bedford Square, W.C.1, and must be completed and returned by January 1, 1939.

The London Emergency Bed Service

At a meeting of the Council of King Edward's Hospital Fund for London on December 13 the president, the Duke of Kent, opened the proceedings by reading a brief message of encouragement from the King. His Royal Highness in his address referred to the various activities of the Fund, including the emergency crisis distribution; the provident scheme for the middle classes, in which the British Medical Association had given valuable assistance; the promotion of a Bill to exempt voluntary hospitals from the incidence of rates; and the distribution of grants, amounting in all to £305,000, to hospitals.

The chairman of the Voluntary Hospitals Emergency Bed Service Joint Committee, Sir Harold Wernher, presented a report on the provision made by that committee, which was set up last summer to facilitate the admission of acute and emergency cases to voluntary hospitals in London, the King's Fund undertaking to provide the necessary finance and supervisory staff. The Joint Com-

mittee of the King's Fund and the Voluntary Hospitals Committee responsible for the Service consists of Sir Harold Wernher, Lord Luke, Sir Ernest Pooley, Mr. O. N. Chadwyck-Healey, Dr. A. M. H. Gray, Dr. Geoffrey Evans, and Mr. A. J. Gardham. (Articles on the work of the Voluntary Hospitals Emergency Bed Service appeared in the *Journals* of June 4 and June 18, 1938.)

A staff of twelve operators was appointed and given a preliminary training with the help of the hospitals. The Service was opened on June 21. Initially it was open from 8 a.m. to 10 p.m. only while the staff gained experience and confidence in their duties. A full twenty-four-hour service was brought into operation on October 8. The Service telephones every hospital once or twice a day according to a special schedule and receives a report of the number of beds vacant; this report is subdivided into some forty categories according to the sex and medical category attaching to each bed. The number of cases presented by doctors has grown steadily and is still growing week by week. By the end of November 2,800 cases had been dealt with. On no occasion has the Service been unable to find a bed for a genuine emergency, and only in exceptionally difficult cases has it taken more than ten minutes to arrange admission. During this time the necessary data have to be given by the doctor, and he has to decide to which hospital where there is a bed available he would like to send his patient. The hospital has to be telephoned and the bed booked, often an ambulance called, and finally the doctor is telephoned to confirm that all is in order. It is estimated that some 25,000 telephone calls in all have been made, the majority of which are concerned with keeping the record of beds up to date. Over 1,200 doctors have used the Service already, and this number grows daily. Many doctors have written expressing their appreciation, and in some cases stating that the life of the patient has been saved by the rapidity of the admission to hospital. The Service has been asked to arrange ambulances for about one-third of the cases it has handled. The procedure has worked smoothly, and gratitude is expressed to the London Ambulance Service of the London County Council and the Home Ambulance Service of the Order of St. John of Jerusalem and the British Red Cross Society for their co-operation. During the crisis provisional arrangements were made for moving the Service to safer quarters in the basement of a large house in the suburbs, but the move did not actually take place. Since then negotiations have been in progress to arrange for these premises always to be available for the Service should evacuation ever become necessary.

A Local Inquiry into Malnutrition

During the year 1938 the Ipswich Committee against Malnutrition has conducted an inquiry into the food resources of more than 100 working-class families, and the results have been made into a pamphlet by Dr. A. M. N. Pringle, who has just retired after thirty-one years' service as M.O.H. for Ipswich. The facts as to family income and expenditure are all carefully tabulated, with the amount available for food set against the B.M.A. minimum. At the end averages are worked out in income groups, with interesting results. It is seen, for instance, that fixed charges (rent, fuel, light, insurances) take a much larger proportion of the smaller incomes: they increase with income, but not to the same extent as food. The average amount per head per week ranges from 4s. 6d. to 7s., though in six cases it is below 3s. Alongside these figures Dr. Pringle gives an interesting summary of the main facts about the effect of nutrition on health and the essentials of a balanced diet, and examines how far these families are able to obtain it. Finally, nineteen food budgets are given in detail, with a comment from the doctor on each one, preceded by general conclusions. Milk is everywhere insufficient, usually very much so indeed; so also are butter, eggs, and cheese. Fruit and green vegetables are only purchased in meagre and insignificant quantities. Protein foods are below standard both in quantity and in quality. Bread is the basic food, and, alas! it is white bread, from which most of the protein and mineral elements have been removed. The results

of this independent investigation bear out the conclusions reached in other areas. Ipswich is a comparatively prosperous town, and the low level of nutrition is possibly not so widespread as in less fortunate places, but it exists there to a larger extent than one would have expected, and the figures show that if the family is not quite small it exists even when the father is in work and earning up to 50s. per week. Copies of the report can be obtained, price 4d. post free, from the secretary, Mrs. Lewis, 41, Brunswick Road, Ipswich, or from the secretary of the London Committee against Malnutrition, 19c, Eagle Street, Holborn, W.C.1.

Chelsea Clinical Society Dinner

The annual dinner of the Chelsea Clinical Society was held at the Rembrandt Hotel, S.W., on December 6. In proposing the toast of the Society, with which he coupled the name of the president, Sir Eric Maclagan referred to the many doctors he had dined with at different times, most notable among them being Sir Clifford Allbutt. The president of the Society, Mr. Duncan Fitzwilliams, in replying, delighted his listeners by presenting a condensed history of Chelsea. He sketched the careers of the many owners of King Henry's Manor and what was known as "Old More's Manor" (the estate of Sir Thomas More). These houses finally became the property of Sir Hans Sloane, at that time President of the Royal College of Physicians, who owned almost all Chelsea, and whose remarkable collection of coins, fossils, manuscripts, and curios formed the nucleus from which the British Museum was created. Dr. Kenneth Eckenstein, honorary treasurer of the Society, proposed the toast of the guests in a characteristically witty speech. Among the guests were the presidents of the Medical Society of London, the Hunterian Society, and the West London Medico-Chirurgical Society. A reply on their behalf was made by Mr. C. W. Gordon Bryan, the honorary treasurer of the Royal Society of Medicine.

Human Milk for Delicate Babies

A National Mothers' Milk Bureau will be opened by the National Birthday Trust Fund at the new Queen Charlotte's Hospital on January 1, 1939. The bureau will be under the supervision of the staff of Queen Charlotte's Hospital, but the cost of maintenance will be borne by the National Birthday Trust Fund. The object of the scheme is to make available human milk for delicate babies for whom it has been medically prescribed. The bureau will be provided with the most modern equipment and freezing plant through the generosity of Sir Julien Cahn, chairman of the National Birthday Trust Fund.

Filming Fracture Work

Now that cinematography has proved its value in medicine we may perhaps have to devote a corner of the *Journal* to "film notes." T. J. Smith and Nephew, Limited, have been at some pains to prepare a film on the functional treatment of fractures, and they claim with justification that it is based on the well-known report on fractures issued by the British Medical Association in 1935. The producers have not entirely concealed their belief that "cellona" plaster bandages are eminently suited to the modern treatment of fractures, but it is fair to say that the film is instructional from first to last. There are about 2,000 feet of 16-millimetre film, and it takes about one and a half hours to show. The four fundamentals of successful fracture treatment—namely, (1) segregation, (2) continuity of supervision, (3) after-care, and (4) unity of control—are covered most admirably in the opening section. Then follow other sections dealing with the treatment of various common fractures, such as Colles's, supracondylar fracture of the humerus, tibia, and fibula, Pott's fracture, crush fracture of a vertebral body, and many others. The film was made at a well-known fracture

clinic, and it is a delight to see portrayed the unhurried efficiency, the thoroughness and care, with which the work is done. It is, perhaps, the one danger of this film that it makes fracture work look so easy. Possibly it is to those who have had long and arduous experience, but the daily price that has to be paid for success is constant vigilance and the most patient attention to detail. Only a few shots show mistakes to be avoided, and rather more warning notices might, perhaps, have been included. As a means of teaching this film has only limited usefulness; as an instructive entertainment it is very good, and as a way of showing just how the thing should be done it is superb. Admitted that there may have been some stage managing (and probably no such admission need be made), this film shows what is actually being done in well-organized fracture clinics, and it is to be hoped that there will soon be more centres that could stand the scrutiny of a candid camera.

IRELAND

Irish Medical Reunion in London

The annual autumn meeting of the Irish Medical Schools and Graduates Association was held in the Rembrandt Hotel, London, on December 1, and consisted of a dinner followed by a dance. The president, Mr. Johnston Abraham, and Mrs. Johnston Abraham received the guests, who included Lord and Lady Stopford and the Rev. Canon Hannay and Miss Hannay. Lieutenant-General William P. MacArthur, the Director-General of the Army Medical Services, was present, and received on behalf of Captain J. W. Orr, M.C., R.A.M.C., the Arnott Memorial Medal, which was awarded by the society to Captain Orr for bravery under fire on the Indian Frontier. Sir William de Courcy Wheeler proposed the toast of the guests, to which Lord Stopford replied, and Canon Hannay (George Birmingham) proposed the toast of the association, and referred to the literary gifts of the president, who is the author of *The Surgeon's Log* and *The Night Nurse*. The dance was enjoyed by the members, their wives, families, and guests.

Honorary Degree for Sir W. Langdon-Brown

The National University of Ireland, on December 8, conferred an LL.D. degree, *honoris causa*, on Sir Walter Langdon-Brown. The degree was conferred by the Chancellor of the University (the Prime Minister, Mr. E. de Valera); and Professor Henry Moore, in an introductory speech, said that while Sir Walter Langdon-Brown's name was familiar to every member of the medical profession through his medical writings and lectures, his reputation was high in literary and scientific circles through his philosophical and scientific works. In addition to holding a leading position as a consulting physician in London he was Emeritus Professor of Physics in Cambridge University.

"He has held the Croonian Lectureship of the Royal College of Physicians of London, and he was the Harveian Orator of the same college. He is the author of several standard textbooks and papers relating to medicine, psychology, and philosophy. His latest book, *Thus We Are Men*, is a masterpiece, wherein, with a purity of English style rarely seen to-day, he discusses life in relation to philosophy and psychology, and in which he shows a deep knowledge of human nature. During the time that he has been attached to this University as Extern Examiner in Medicine his colleagues have grown to appreciate deeply his scholarly attainments."

After the conferring of the degree Sir Walter Langdon-Brown gave a lecture at University College, Dublin, entitled "Medicine—Yesterday, To-day, and To-morrow." It was attended by the Prime Minister, and the President of the College, Dr. D. J. Coffey, was in the chair. There were almost 400 people in the audience and the lecture was applauded for several minutes at its conclusion.

Ulster Medical Society

At the meeting on November 17 of the Ulster Medical Society, the president, Dr. J. McCloy, in the chair, Professor J. H. Biggart read a paper on diabetes insipidus. After briefly describing the history from the early knowledge of Willis (1674), the discoveries of Claude Bernard, the experimental work of Schafer and Hering, and the clinical observations of Farini and van der Velden, the speaker dealt with recent experimental work and the anatomical findings in eight human cases. In five of these eight cases, he said, pituitrin controlled the polyuria, and in each of these the lesions found were so localized as to interrupt the supra-optic-hypophyseal nervous tract to the pars nervosa, and had destroyed completely this part of the pituitary gland. In two of the cases the damage to this nerve pathway had resulted in marked atrophy of the pars nervosa, suggesting that the pathway had a definite influence on this structure. In three patients the polyuria was not controlled by pituitrin, the lesion involving not only the anterior hypothalamus but extending sufficiently to destroy the nuclei of the tuber cinereum. The syndrome had been experimentally reproduced in fourteen dogs, and the findings in these animals supported the suggestion arrived at from a study of the human material that interruption of the supra-optic-hypophyseal tracts resulted in a cessation of the manufacture of the anti-diuretic hormone. Studies of human cases and experimental material also showed that the anterior pituitary played an important part in the development of the syndrome.

INDIA

Madras Ophthalmic Hospital

A triennial report and statistics have been issued for the Government Ophthalmic Hospital, Madras, for the years 1935-7. Plans were drawn up for the construction of new quarters for the nursing staff, an extension and ticket hall for the out-patient department, and a dining hall for patients, at a total estimated amount of 43,000 rupees. There was but little change in the numbers of patients treated during the period under review, and the nature of the diseases treated was much the same as in 1936, some details of which were given in the *British Medical Journal*, 1937, 2, 550. Over 100 medical students were trained in each of the three years. This institution has a wealth of varied clinical material, but its accommodation is at times very severely strained.

Enteric Fevers in the Armies

A point of special interest in the second volume of the report for 1936 of the Public Health Commissioner with the Government of India is the low incidence of enteric fevers in the armies, which was particularly striking among Indian troops. Part of the reduction among enteric group cases was possibly due to better diagnosis of the mild typhus group cases, but it is added that this factor is inapplicable to the great reduction in both typhoid and paratyphoid A group (Indian) which occurred during that year, while the ratio for typhus fever (Indian) is the same as that for 1934 when the figure for enteric fever incidence was the lowest on record. The number of deaths in both British and Indians from enteric fever was also greatly reduced. There was no corresponding reduction among the civil population but rather an increased incidence, nor have there been any striking changes in the general hygiene of military areas. Growing interest, however, is being taken in child welfare among their families by all Indian units, and many enteric cases were detected which would otherwise have escaped notice, suitable treatment being given at once. Another focus of infection is thus being eliminated. Special note is made of the improvement in the T.A.B. vaccine supplied by the R.A.M. College and the Central Research Institute, Kasauli, during the last few years. In the 1935 report attention was called

to the increasing number of apparently ambulant infections among the fatal typhoid cases. For the total enteric group of fevers the statistics are similar to those of previous years for the various post-inoculation periods, but in the bacteriologically proven cases there was in 1936 a considerable fall in the percentage of cases occurring in the first six months after inoculation, and a definite rise in the twelve to eighteen months period. The results obtained by agglutination tests were again inconclusive in both "H" and "O" agglutination. Comparative tests of Dreyer's technique and that of Felix with standardized T.O. suspensions had not yet yielded sufficient data for definite opinions except that in the great majority much higher titres of "O" agglutination were shown to be present by the second method.

During 1936 the admission ratio for dysentery fell by 4.6 per 1,000, being the lowest for many years, but this was offset by an increase in the admissions for diarrhoea and colitis, leaving a decrease of 1.4 per 1,000 for the whole group of diseases. Reduction also occurred in the admissions for amoebic hepatitis, and only two cases of liver abscess were admitted. Cases were as usual sporadic, and the greatest incidence corresponded with the fly season. It was observed that units arriving recently in stations after train journeys produced small crops of cases. It is reiterated that this group of diseases is, under peace conditions, largely passed on from the insanitary conditions prevailing among the civil community. The striking range of the fly and the absence of any reliable method of producing active immunity against the numerous varieties of dysentery bacilli prevalent among the population of India account mainly for the fact that the admission rate to hospital among British troops in India in 1936 was as high as 42.1 per 1,000, compared with an admission rate of 1.5 per 1,000 for the enteric group of fevers.

Opium Smoking in India

Brevet Colonel R. N. Chopra and Mr. G. S. Chopra have published in the *Indian Medical Gazette* a series of articles on "The Opium Smoking Habit in India." The history of the custom, which was prevalent in China from the beginning of the seventeenth century, but not in India or Persia until the nineteenth century, is related. Smoking, as opposed to eating, opium has not been largely prevalent in the Dependency except in Assam and Burma. It obtains mostly in the larger towns and among the poorer inhabitants. In 1932-3, 28,448 lb. of opium were consumed in Assam, or 30 lb. per 10,000 of the population. The ratio of smokers to eaters in Assam is 1 to 4. The former are more numerous in the hilly country than in the plains. Addicts are as 1 to 126 in the population, but the number is declining under Government restrictions and registration of smokers. In Burma opium has been in use for 300 years, and in 1933 there were 53,000 opium eaters and smokers in that country. The official view is that opium smoking is a social vice, and Colonel and Mr. Chopra recall the view of the Royal Commission of 1895 that the eating of opium is relatively harmless compared with opium smoking. It is also much cheaper, since it is stated that the effects of smoking 180 grains a day can be obtained by the ingestion of 10 grains. The objective sought after is a state of euphoria, and it is the quest of the poor and miserable as an escape from their surroundings. Smoking is mostly resorted to in company in dens, sometimes with social functions or quasi-religious observances. Opium eating, on the other hand, is practised alone and often furtively; but the habit is more easily cured than is that of smoking. The authors appear to share the official view that a great distinction is to be drawn between the effects of eating opium compared with those of smoking; nevertheless they observe that "no scientific data are available to support the view that smoking of opium is more harmful than eating to the individual addict."

Correspondence

Surgical Approach to Facial Neuralgia

SIR,—I was profoundly impressed by Mr. G. F. Rowbotham's paper on the treatment of pain in the face by intramedullary tractotomy in your issue of November 26 (p. 1073).

What impressed me was not that the pain had been relieved (it should be, if our anatomy and physiology books are reliable) but that he was able by his analysis of the patient's description of certain subjective sensations to make a diagnosis of "primary" pain, apparently without having searched for those pathological conditions in the area subserved by the sensory branches of the trigeminal nerve which are commonly found to be productive of any and every type of pain in the face. I hope that Mr. Rowbotham will assure us that he carried out an exhaustive examination of the nasal sinuses and the teeth before he made his very skilled inroad into the central nervous system.

If he is in the habit of taking the quality of the pain (as described by the patient) for a guide as to its "primary" nature, I would refer him to the very interesting observations upon somatic pain recently recorded by Sir Thomas Lewis (*British Medical Journal*, 1938, 1, 321), which indicate how misleading a patient's description of pain may be.

Sluder (*Trans. Amer. laryng. Ass.*, 1912, 35, 42) painted the interior of the sphenoidal sinus with 20 per cent. cocaine and found that the whole of the face on the same side became anaesthetized, an observation which emphasizes the intimate anatomical relation between this sinus and the Gasserian ganglion. It helps to explain how absorption of toxins under pressure from a blocked sphenoidal sinus can inflame the ganglion of the trigeminal and lead to pain anywhere in its distribution. Since sphenoidal sinus work has become a commonplace of rhinological practice, it is so usual to find that facial pain can be relieved by adequate sinus ventilation that one had forgotten that there were still medical men who believed in essential neuralgia. I submit that the word "primary" in connexion with pain is inapplicable; and I would suggest that an experienced rhinologist might be allowed to examine pre-operatively the next case which Mr. Rowbotham has marked down for a procedure which, as he so rightly remarks, "makes an interesting neuro-anatomical experiment."—I am, etc.,

London, W.1, Dec. 5.

BEDFORD RUSSELL.

Cancer of the Breast

SIR,—Mr. G. Gordon-Taylor's recent address on cancer of the breast (*Journal*, November 26, p. 1071), with his follow-up of cases operated on in the last thirty years, shows results which are indeed remarkable, especially so with an 84 per cent. survival rate in Stage I cases after ten years. The fact that these results were achieved by surgery alone without ancillary treatment by deep therapy will be disturbing to many who, like myself, have been accustomed to send all cases for post-operative irradiation.

There are two points on which perhaps one might venture to criticize Mr. Gordon-Taylor's figures: in the earlier cases, say before 1925, some cases were probably rejected as inoperable and therefore do not appear in

the totals. These cases would affect particularly the Stage III group, to which most of them belong, and for comparison with modern statistical tables compiled by radiation centres these inoperable cases must be added to the totals in computing the percentage of survivors.

There is another point: the difficulty of accurately "staging" cases into groups is a very real one to get comparable figures for comparison between different methods of treatment. The division between Stages I and II, depending on whether axillary glands are present or not, is a reasonably precise one. The division between Stages II and III is less precise, and if (as I presume) staging in Mr. Gordon-Taylor's cases was based on the notes of the cases and not definitely carried out at the time of examination, some confusion might easily arise in differentiation between these two groups. If this were so, then his results in both Groups II and III would be vitiated to some extent by the failure to include the inoperable cases. Thus the figures of 25.2 per cent. survivors at the end of ten years and 35.3 per cent. five-year survivors, which are obtained by combining Mr. Gordon-Taylor's Group II and Group III cases, should in reality be considerably lower.

A survival rate of 84 per cent. after ten years from such an unexceptionable source and by surgery alone is of the utmost value as a standard of what can be achieved, and helps to clarify one's ideas for future comparison with the combination of surgery with radiation in breast carcinoma.

The Group III case benefits enormously by radiation; Mr. Gordon-Taylor recognizes this inasmuch as he has sent twenty-eight such cases for radiation alone between 1925 and 1935. The Group II case in my experience has benefited considerably by post-operative radiation, though it is too early yet to give figures extending over a sufficient period of time to judge the final results.

With regard to the Group I cases, like Mr. Gordon-Taylor I rely on surgery, but in addition give post-operative radiation. I have often wondered whether it was necessary in these cases—the figures which he gives incline me to think that it is not, and that in the ordinary Group I case reliance can be placed on surgery alone, and post-operative radiation is unnecessary.—I am, etc.,

Birmingham, Dec. 9.

SEYMOUR BARLING.

Neck Plaster

SIR,—The very interesting article by Mr. John C. Nicholson in the *Journal* of August 27 (p. 464) describing his experiences as a patient encourages me to write and say how fully I agree with his remarks about the cold wet plaster. In February last I had a motor-car accident which I did not regard very seriously, thinking I had escaped with two broken ribs and some bruises, but eventually I had my neck x-rayed, the film revealing fractures of the transverse processes of the fourth and fifth cervical vertebrae. Although this was nearly a month after the accident it was decided that I should go into plaster as I was still getting so much pain.

I cannot remember how many patients I have told not to fuss about their plaster, but having had one put on—even in the dry heat of Rajputana, with the thermometer at 108° F.—I shall never do so again. I shall never forget the misery of the wet, cold, and irritating plaster round my neck and head. Mr. Nicholson is perfectly right in his references to the little pieces of plaster which cause so much irritation, and which in a neck plaster are inevitable owing to the movements of the lower jaw. I must admit that after a few days I

had my plaster removed and put myself into a splint in the shape of a cross, which I wore for some weeks. It did not interfere with my work, except that cystoscopies were difficult as one could never get one's eye at the right angle. With a stiff neck ordinary surgery, both abdominal and ophthalmic, was perfectly easy, as one learnt to bend from the hips very quickly.

Never again shall I inflict on a patient a neck plaster if it is possible to fix him adequately with splints, which I believe to be the case if one pays sufficient attention to the details of their manufacture and fitting.—I am, etc.,

E. W. HAYWARD,

Rajputana, Nov. 22.

Principal Medical Officer, Jodhpur.

Adrenaline Treatment of Asthma

SIR.—Dr. Alexander Francis's experience regarding the removal of polypi in aspirin-sensitive (December 3, p. 1179) agrees with mine. The removal of bone in them is usually disastrous. These patients have in an unusual degree the capillary permeability characteristic of allergy. At operation their noses flood with blood and the field is hidden. But the polypi have to be removed. They should not be tackled, however, till the patient has had a course of general treatment for a month or two. This includes an organic compound of calcium plus vitamin D but minus milk. Such treatment has served me well with a retired Army officer, asthmatic and aspirin-sensitive. The polypi recurred until this treatment had time to act, and also until I used ionization with a zinc needle buried in any buds that threatened to develop into polypi. The patient has now neither asthma nor rhinorrhoea. He never needs adrenaline.

That raw milk is a fertile source of asthma I have found for forty years. But it is not generally known that, short of asthma, it may cause rhinorrhoea. Milk rhinorrhoea has become common since the institution of "seltool milk." That raw milk should be stopped before trying the removal of the stellate ganglia for persistent rhinorrhoeas—as has been recently done to a lad who persistently took milk—does not seem to dawn on the rhinologist, nor the need for stopping it in treating hay fever. Other vitamins than D are of course important, and it is possible that foods rich in vitamin K—cabbage, spinach, liver—may be specially helpful because of the importance of this vitamin in the formation of prothrombin.—I am, etc.,

Glasgow, Dec. 4.

JAMES ADAM.

SIR.—I would like to thank Dr. Alexander Francis (*Journal*, December 3, p. 1179) for his courteous reply to my letter and for giving full particulars regarding the patient under discussion. As a matter of fact, I entirely agree with him as to the inadvisability of indiscriminate removal of polypi, but have certain suggestions to offer in response to his request.

1. Careful analysis, as recommended by Maxwell, to determine the prime source of the attacks. Maxwell's classification is, incidentally, as follows: (a) an allergen (bacterial; non-bacterial; bacterial plus secondary non-bacterial; or non-bacterial plus infection or toxæmia); (b) nasal; (c) bronchopulmonary; (d) alimentary; (e) endocrine; (f) psychological.

2. Nasal endoscopy by a competent rhinologist—to avoid missing a latent sinusitis. Sphenoidal and post-ethmoidal sinusitis frequently play a part in the production of allergic manifestations, and are almost invariably missed by the ordinary rhinoscopies. Suspicious findings demand suction lavage and bacteriological examination of the washings.

3. The protein metabolism may repay investigation. Lapage and Dzinich hold that the liberation of histamine is the deter-

mining factor in the allergic reaction, while the former points out that circulating amino-acids and other toxic bodies irritate the autonomic nervous system.

4. Maintenance of the proper balance of potassium and calcium in the tissues and perfect endocrine balance both affect the irritability of the parasympathetic, according to Fraenkel and Bray; therefore any abnormality found should be corrected.

5. Sunshine, ultra-violet light, x-ray therapy, and cold douching after hot baths increase the output of adrenaline, so helping to stabilize the autonomic nervous system; while nerve tonics such as zinc valerianate and liquor arsenicalis may be helpful.

6. Strict dietary control is advised by Jay to avoid overloading metabolism or including "allergenic" constituents.

7. Auto-genous vaccines are of very limited use (Bray, Theodore Just, and Frederico Nitti).

8. The fact that cutaneous and mucosal sensitivities do not run parallel courses and the changeability of sensitivity from time to time and from place to place negative the value of cutaneous tests and render desensitization rather futile (Bray and Chandler Walker).

9. Small doses of codeine and the giving of a sedative linctus at night are respectively recommended by the same two authors.

10. Sclerosing submucosal injections benefit a number of cases provided there be special indications.

11. Cauterization of sensitive areas is not a very popular measure, though W. Howarth claims improvement in 50 per cent. of asthmatics.

12. Intramucosal auto-cerotherapy and intravenous peptone have their supporters.

13. Surgery, except for sinusitis when satisfactory results are to be expected, should be extremely conservative (Bray, van Lennuven, Gill Carey, Moll). A submucous septal resection may leave an irritable ethmoid, while hypertrophic masses and hyperplastic sinus disease should be left severely alone; tonsils should only be removed if definitely infected. Lastly, Chandler Walker, Bray, Lapage, and others all agree that good results follow the removal of septic foci in cases of asthmatic bronchitis.

I hope that some of these suggestions at least may recommend themselves to Dr. Francis, and that with their adoption considerable relief may be afforded the patient.—I am, etc.,

Bath, Dec. 6.

C. A. HUTCHINSON.

Cyclopropane and Pulmonary Atelectasis

SIR.—During recent years there has been much discussion concerning the causation of post-operative pulmonary complications. It has been suggested that certain anaesthetic mixtures, such as cyclopropane and oxygen, which contain an abnormally high proportion of oxygen may lead to atelectasis or even major pulmonary collapse, either at the time of operation or subsequently during the post-operative period of recovery. This is due to the fact that oxygen is absorbed from the pulmonary alveoli much more rapidly than atmospheric air. To what extent this statement is true it is difficult to assess, as there are so many other factors involved in post-operative pulmonary collapse. Heavy premedication, obstruction of the airway, post-operative mechanical difficulties in respiration, bronchial spasm due to reflex irritation set up by too high a concentration of ether or (in certain cases) an endotracheal tube, must all play their part, while the current practice of producing an artificial apnoea in order to facilitate the work of the surgeon would appear to be not without danger to the patient.

During the administration of cyclopropane anaesthesia the patient inhales a mixture of gases containing anything up to 90 per cent. of oxygen. After a long operation this over-oxygenation is liable to result in unpleasant

after-effects, such as headaches, nausea, and possibly even mental symptoms in some cases. Moreover, unless the anaesthetist is careful to lower the oxygen percentage by easy stages towards the end of a long operation, the patient may suffer extreme shock on suddenly being transferred from 90 per cent. oxygen to atmospheric air. In order to overcome these objections it is quite easy to administer cyclopropane with ordinary air.

A Y-piece is incorporated with the rubber tube leading to the oxygen flowmeter of a Boyle's apparatus, one limb being connected to the oxygen supply cylinder and the other to a double-bellows as used for Shipway's apparatus. By adjusting the tap on the oxygen flowmeter and squeezing the bellows a steady flow of air at the rate of 1 or more litres a minute may be maintained for any length of time. If desired, a special flowmeter calibrated for air may be fitted to the Boyle's apparatus. During the induction of anaesthesia the rebreathing bag should be about two-thirds filled with air before starting the cyclopropane. Oxygen can be dispensed with altogether, but in practice it is better to adjust the flow of oxygen at the rate of 200 or 300 c.c. a minute, according to the metabolic requirements of the patient. Subsequent losses due to leakage should be made up with air by means of the double-bellows. Incidentally, by using this technique with the Waters's carbon dioxide absorber the air is delivered direct to the face-piece and thus is not contaminated by the contents of the rebreathing bag.

To prevent misunderstanding, I would like to emphasize that I do not claim any originality in administering cyclopropane with air. It seems reasonable, however, to suppose that the human respiratory system has been evolved expressly for the purpose of inhaling ordinary atmospheric air; whereas the modern tendency of anaesthesia seems to be directed to compelling the patient to inhale anything except this universal and convenient gas, thus contravening the laws of physics and physiology.—I am, etc.,

Newcastle-upon-Tyne, Dec. 5.

PHILIP AYRE.

Correct Footwear

SIR,—I am glad to see that at long last someone else has taken up the question of women's shoes and the results that occur from the unsuitable examples of footwear thrust on the female population, pandering to their vanity. I have been interested in the matter for some years from the public health point of view, and only at the end of October, just before I retired, I examined the heels of nearly 2,000 children in the schools of my district. I classified them into three grades of malformation, according to the extent to which the heels were worn and causing the stresses in the foot to become abnormal, and according to the degree of abnormality of the foot causing the heels to wear abnormally. I found a few of the children's heels were so bad that they were completely worn on the outer side, making an angle of 45 degrees, and I had to add two more categories, making five in all. The number of abnormal cases was very high, and for some so far unknown reason was much higher in the normal upper school than in the large central school for children of slightly lower mental attainments.

My attention was first drawn to this matter by watching the waitresses in large multiple tea-shops in London. Some of these in the late evening were to be seen hobbling about, tired out as the result of the pain produced by their footwear. In all these cases the heels were worn on one side, mostly the outer, and it was obvious that the constant abnormal strain was the *fons et origo mali*. One large multiple store that I approached considered making shoes of a standard pattern part of their employees'

uniform, but the girls refused to wear anything but a "court" shoe with a needlessly high heel. Vanity ruled the situation.

Anyone who looks at the heels of the crowds in the streets will be amazed at the number of bad heels there are, particularly among the poorer members of the community. I had the idea that much of this might be due to buying second-hand shoes or the handing down of shoes in the family, but the number of cases of this I found was far less than I expected. The psychological damage is often considerable, as the victim seems to think that everyone behind her is looking at her heels. She cannot get away from the fact as, in order to keep her feet decent, she has to buy many more pairs of shoes than her more fortunate sister. A point often overlooked is that these very high heels throw the body balance out completely, and produce stresses and strains far from the feet. When Dr. T. Marlin says (*Journal*, December 3, p. 1159) that "high heels seem to be necessary for about 90 per cent. of our womenfolk" he is merely stating that the necessity is dictated by vanity and nothing else. When I refer to high heels I do not mean the heel of 1½ inches of the "Cuban" type, but the 3-inch or so peg-top, which gives no support save to a perfectly normally balanced foot. Another contribution to the deformity of the shoes is dictated by the ignorant bootmaker, who puts rubber tips on the outer side of the heels of these unfortunates. What they want is support and not a yielding outer edge, which only hastens the deformity of the heel and with it the shoe. A man's shoe requires a double row of large flat-headed nails; a woman's heel smaller nails on the outer side and frequent repair. For the cheaper shoe the man can have a metal heel which can be easily replaced; the trouble is that they are not replaced early enough. Very high heels often deform not only the shoes but ultimately the feet by pushing the toes right forward and crowding them into the front of the shoes. Vanity, vanity, all is vanity!—I am, etc.,

Officers of Health.

The Blood Platelet

SIR,—Referring to your leading article on the blood platelet in the *Journal* of November 26 (p. 1090) it must seem an intrusion on the part of a general practitioner to offer any comment. But the article, with its record of an immense amount of investigation which has so far produced no definite conclusion, naturally makes any medical man wonder why this should be so, and whether it may not be that the formation of the blood platelets is to be sought and found in the blood plasma itself instead of in the bone-marrow, spleen, and lungs. There are myriads of protein particles in the blood plasma. Is it not likely that some change in their relations forms the platelets? And now there follows a letter (December 3, p. 1179) from Mr. J. E. R. McDonagh, who has for many years made a critical examination of the blood and plasma. His views appear to be rational and logical, and are supported by his experiments and research. It would be of interest to have them confirmed and accepted, so that the problem of the blood platelet might be concluded. Mr. McDonagh's studies throw a new light on the problems of medicine in all directions, to my mind, and he reads deeper into the fundamental nature of things than any other investigator does. Further light on the many questions involved would be welcome.—I am, etc.,

Glasgow, Dec. 7.

R. O. ADAMSON.

Play Therapy and Child Guidance

SIR.—It is encouraging to those of us whose work lies in the sphere of child psychology to read so wise and sympathetic an appreciation of the value of play therapy for children as was expressed in your leading article in the *Journal* of December 3 (p. 1150). Whereas it is not contended that there is, or should be, only one form of play therapy, it is important for the wise development of this treatment, as of any other, that different forms of this therapy should be distinguished and their origin and evolution known.

Play therapy for children in England arose from two sources. On the one hand, Mrs. Klein and her pupils have used play as the instrument of treatment for children in this country within the psycho-analytic school since 1927. The results of this form of therapy obtained with clinic children are set out in the *Decennial Review of the Institute of Psycho-Analysis*. All psycho-analytic treatment is given individually. Play for group treatment of children in clinics as a method was created in 1928 in the opening of the Institute of Child Psychology (then called the Children's Clinic), having arisen parallel with, but independently of, psycho-analysis. At this time, though the Child Guidance Council had been formed, there was no clinic under the Council in this country; the one existing child guidance clinic (the East London Child Guidance Clinic), one month older than the I.C.P., was under the Jewish Board of Guardians. There was no play at this clinic then, nor in the London Child Guidance Clinic, opened a year later. In 1933 a member of the staff of the I.C.P. joined the staff of the Tavistock Clinic and became its first "play therapist." In 1935, at the request of the West End Hospital, a therapeutic playroom was opened in that clinic under the direction of the I.C.P. in co-operation with the director of the hospital clinic. The methods in use at the Institute of Child Psychology were published in the *British Journal of Medical Psychology* (1931, 11, Part III), in the *Medical Women's Federation News-Letter* (July, 1938), and *Play in Childhood* (Gollancz, July, 1935). There are, therefore, two clearly formulated methods of play therapy, each with its own theory and technique.

Various child guidance clinics have established playrooms in recent years. It is not yet quite clear whether it would be more accurate to say that the children in these clinics play, or whether systematic play therapy is the therapeutic corner-stone, as is the case with child psycho-analysis and the work of the Institute of Child Psychology. No description has been published, and it is therefore difficult to judge. This distinction is not a mere verbal quibbling, since in evaluating results it must be clear to what method of treatment they apply. In your article you regret the lack of statistics in relation to results of therapeutic play. May we remind you that in your issue of July 30 of this year you published a statistical paper on play therapy for "problem" children, giving the immediate and late results of play therapy as used at the I.C.P. over the period from 1930 to 1935, and that a careful demonstration of results obtained from this form of treatment formed part of the Exhibition of the International Medical Congress for Psychotherapy, Oxford, 1938. As with all medico-psychological work, careful theoretical and practical training is essential for those who are to undertake play therapy. For the last five years a systematic course of theoretical and practical training has been held at the I.C.P., which is designed to provide other clinics with qualified workers for this type of treatment.

There are three statements in your article upon which we should like to comment. "It does not appear suitable for the majority of delinquents over 10 years old, although in some of these cases it has proved useful." This is not borne out by our experience at the I.C.P. We find that, when suitably handled, delinquent children of all ages respond favourably to this form of treatment. No one could appreciate more highly your statement that "much caution must therefore be exercised in putting forward claims for cure when all that has happened is that therapy has coincided with the natural resolution of a transient disturbance." We note also that you state that severe cases are found not to be suitable for group play therapy, but need instead individual treatment. This again has not been our experience, and among the cases put forward in the statistical paper quoted above are included cases of personality deviation, profound debility, and anxiety states which have been present for a number of years and which have been successfully treated by group play therapy, according to the methods used at the I.C.P.—We are, etc.,

Treatment of "Angina of Effort"

SIR,—I have read with great interest Dr. R. H. Dixon's article on cure or relief of cases misdiagnosed angina of effort (*Journal*, October 29, p. 891), and I am very glad that he has come to the same conclusions as have several writers before him. An article on angina pectoris, by W. von Althaus, appeared in the *Tidskrift i Gymnastik*, the official journal of the Swedish gymnasts, during 1901, in which he described three cases of the disease in which cellulitic (that is, fibrositic) areas were found, the removal of which by massage promptly cured the angina. Dr. Wetterwald of Paris also described the same on several occasions, and personally I have had cases which were of the same nature.

I would, however, like to add that sometimes the removal of fibrositic areas is not enough *per se*, but if combined with cervico-dorsal "mobilization" a cure will then result. I have found that a number of patients with functional disorders of the heart, including pseudo-angina, suffer from being very round-shouldered and have, in consequence of long years of disuse, practically lost the power of movement in the region mentioned. Thus many of the nerves connected with the heart come to lie in an area which is practically immobile, and thus perversion of their function may ensue. (For further details see *J. chart. Soc. Mass.*, 1934, 20, 7; and *Res. Quart. Amer. phys. educ. Ass.*, 1936, 7, 74.) Restoration of movement in this locality has nearly always gone hand in hand with improvement in the cardiac symptoms.—I am, etc.,

London, W.1, Dec. 7.

EDGAR CYRIAX, M.D.

Acute Bulbar Paralysis

SIR,—I was greatly interested in the paper by Drs. D. M. Anderson and J. H. Dixon with the above title in the *Journal* of November 26 (p. 1077).

Fairly recently I saw a patient who almost completely resembles the cases described in this article. At the end of July and in the early part of August four cases of acute anterior poliomyelitis were brought to my notice, all occurring in the same village. Three of the children represented mild forms of the disease, and not at any time did one fear a fatal ending. Each of these children exhibited paralysis of a limb. The

fourth child died. This last patient was a girl aged 6½ years. On July 15 she had a tonsillectomy performed and was soon apparently well and about. On July 30 she complained of severe headaches. The following day she seemed better but complained of a sore throat, and on careful inquiry this seems to have been rather a difficulty in swallowing than any painful condition. On August 1 she still complained of headache, and swallowing became almost impossible. She was sent to the isolation hospital by the practitioner as a "laryngeal diphtheria." On admission the throat was clear but there was much copious mucous secretion, some respiratory stridor, no cyanosis, pulse 156, constipation. On August 3 there was noted a marked neck rigidity, swallowing of fluids was impossible, Kernig's sign was present, and the plantar responses were of the extensor type. During the day the child became cyanosed and had convulsive attacks, and in the afternoon she died. The final diagnosis was acute polio-encephalitis.

The chief difference between this instance and that of the cases described by Drs. Anderson and Dixon was that the onset of the disease was fifteen days after tonsillectomy, but there are several points of similarity—namely: (1) other cases of acute anterior poliomyelitis were known to be present in the same area; (2) that this child had had a recent tonsillectomy performed; (3) dysphagia was a prominent symptom; (4) the disease was fatal; (5) the condition was that of an acute polio-encephalitis.

After reading the experience of Dr. D. M. Anderson and Dr. J. H. Dixon and the more personal experience described above, I do not think that I would allow a tonsillectomy to be performed on my child during a period when acute anterior poliomyelitis was assuming anything like epidemic proportions.

I am indebted to Dr. D. C. Evans and Dr. E. G. Munro Jones, medical superintendent and assistant medical superintendent respectively of the isolation hospital, for clinical notes after the admission of the case to hospital.—I am, etc.,

A. R. CULLEY,
Medical Officer of Health.

Carmarthen, Dec. 8.

New Menstruation Toilet

SIR,—A number of letters have appeared in your columns at different times referring to the internal sanitary pad. None of these has made any distinction between the (marine) sponge pad, covered with a fine layer of rubber at its external end, sponsored for some years now by certain firms dealing with feminine "beauty" preparations, and the reinforced cotton-wool tampon.

The sponge pad is soft, extremely comfortable, and absorbent, and when carefully introduced so that its upper end lies in front of the cervix can do no mechanical harm. It was first brought to my notice by a patient who found it the greatest boon in hunting. It would be difficult, however, on second thoughts, to imagine anything more repellent than this invention, since it is intended for repeated use (its price varies, according to size, up to 10s.), and women are invited to remove it at convenient intervals during the day, squeeze its contents down the wash-hand basin, rinse it under the tap, and reinsert, a cake of soap being supplied for occasional more thorough "cleansings." The woman who has this pad with her may feel extraordinarily "independent," but it has astonished me that particular criticisms of this method of "hygiene" and reports of infection resulting from the use of such pads have till now escaped appearing in the medical press. Perhaps the sponge pads have never become widely popular, but physicians who are asked for an opinion of the internal pad should not fail to keep in mind the possibility of this type being meant. On the grounds of cost they

might appeal to some patients, since, leaving out the risks of infection, they would certainly appear to work out cheaper than other kinds over a period of time.

The other type of internal pad with a cotton-wool basis is firmer, less easy to introduce, less adaptable, and less absorbent, and even in patients accustomed to wearing internal pads may be very painful. It is undoubtedly a more sanitary invention than the last (since it is removed to be destroyed), but what are its precise advantages, one asks, in patients who can (or who have to) adopt such means of internal protection, over the pad long used by theatrical artists, ballet dancers, and probably the majority of women on the Continent—namely, a little self-made roll of cotton-wool about two inches long, thick according to convenience, perfectly soft and adaptable, highly absorbent, inserted just within the vagina not high enough to get "lost," easy to remove and replace a dozen times a day, cost negligible?—I am, etc.,

London, S.W., Dec. 6.

MARGARET EMSLIE.

SIR,—I was interested to read the comment of Dr. E. Lawton Moss (November 26, p. 1113) on the use of absorbent tampons during menstruation instead of sanitary pads. Curiously enough, I have encountered during the past week a case of particularly bad vaginal and cervical infection which the patient herself attributed to the use of such tampons. While it is unlikely that the tampons were the cause of the original infection, it seems more than probable that they were responsible for the unusually severe development of the condition. It does seem necessary that some warning should be given against the non-medical use of vaginal plugs, especially where there is already any suspicion of infection.—I am, etc.,

Leicester, Dec. 7.

C. HAMILTON WILKIE,

Leicester.

Decline of Breast-feeding

SIR,—It seems a pity that no medical woman with personal experience of breast-feeding has yet taken part in the most interesting correspondence following Dr. J. C. Spence's admirable article. It is in the hope that others, perhaps with more extensive experience than I, will follow my example that I am now writing. I have breast-fed my two children in spite of the efforts of nurses who were wise and kind, and indeed excellent in every way except in their management of the nursing mother.

The nurse tends to make breast-feeding a major problem. Every feed becomes a battle in which the child is constantly stimulated by pinches and pats; the breast is handled and the nipple gripped and thrust into the infant's mouth in a way which is physically uncomfortable and arouses a quite unreasoning resentment; the attitude is that the nurse and the child are the active parties, the mother merely a substitute for the bottle. All this makes breast-feeding unpleasant, and it is not until she is herself in control and can allow the infant to feed unhurriedly and undisturbed that the mother can find any satisfaction in it. Its effect on the infant is probably equally pernicious. I do not know how many women limit the duration of feeds; I suspect that one of the advantages of breast-feeding (when the supply is adequate) is that the infant takes as much as he wants instead of as much as he ought, theoretically, to need.

In the later weeks of pregnancy and the puerperium the nipples are extremely sensitive, and any handling is objectionable. The discomfort, often severe, which occurs in the first two weeks of breast-feeding is due not to "tender nipples" but to a spasm of the ducts. This is shown by

the fact that the pain is not felt when the infant grips the nipple but a few moments later, when the milk begins to flow. An identical sensation occurs sometimes during a hot bath, and it is then seen that a stream of milk is being forcefully ejected. I think this is important, because it implies that the whole conception of "hardening" the nipples may be fallacious.

The other thing I have learned is that the supply of milk is unaffected by most of the conditions usually cited (I exclude gross undernourishment, severe exhaustion, and a feeble infant, since these are outside my experience). It is probably dependent entirely on endocrine factors, and is certainly related to the menstrual cycle. During five months of lactation I had epimenorrhoea; before each period the supply of milk was enormously increased, so that neither breast was ever emptied; this increase persisted for about a week after the period. During the normal amenorrhoea of lactation the menstrual moulins were present, and there was always a similar accompanying increase in milk supply; in the mid-week of the cycle the supply diminished to such an extent that complementary feeding was considered, but was so resented by the infants that it was abandoned. Instead, the situation was met by increasing the frequency of the feeds; by this means the total yield was probably unaffected, but the infant was much happier, and as the supply increased he no longer demanded the extra feeds. After the first four months of lactation the variation in the yield became less marked (although it was still present), and it was then that the "symptoms" of lactation appeared: hair tending to stand on end, to fall out, and to lose its colour, and insomnia and irritability—curiously like the symptoms of hyperthyroidism.

Although successful breast-feeding is to be aimed at, yet bottle-feeding is infinitely preferable to breast-feeding which is a struggle. There can be few things more worrying than the uneasy fear that the infant is being underfed.—I am, etc.,

Dec. 8.

M.B., M.R.C.S.

SIR,—Miss Mary Cunnane's letter (November 26, p. 1112) in my opinion does not so much "challenge" my remarks as lend them force. She apparently accepts the opinion that there is too much wrongly timed and wrongly arranged interference with mother and baby in hospitals, and probably quite rightly puts this down to the exigencies of institutional treatment in general; but she feels that all this is different in the patient's own home. Yet at the beginning of her letter she writes: "Even if, as he says, the modern nurse takes full command of her patient's baby, it is surely a sign that there is something wrong with the system," etc.—and that is precisely what I was trying to make clear.

Her happy picture of how things go in a confinement at home does fit in often with puerperia where the district nurse comes in once a day, but even then the woman is often upset by the cares of an inadequately staffed household. When, however, the household is taken off her hands, then it is usually the case that she has a resident nurse all to herself; and it is those people that I had particularly in mind when I wrote my letter. Why on earth in such cases, where there is the whole twenty-four hours of the day available, should, for instance, a poor woman be awakened before daylight, made to use a bed-pan, fussed over and bullied, and then be expected quietly to provide milk for her infant? It is psychologically wrong, but is only one example of nursing obtuseness.—I am, etc.,

Air Raid Precautions

SIR.—A study of the numerous letters on air raid precautions published in the *Journal* since the crisis shows that the writers are, almost without exception, gravely concerned at the almost complete lack of bomb-proof aid posts, casualty clearing stations, and civilian shelters in our cities.

That other countries are less backward in these respects was clearly shown during the debate on medical services in civil defence in the House of Commons on November 30, in the course of which Mr. Oliver Simmonds, M.P. for the Duddleston Division of Birmingham, who is also chairman of the Parliamentary Air Raid Precautions Committee, stated that he had recently had the opportunity of investigating medical defence arrangements in Paris, and had found that, even before the crisis occurred, in over thirty of the districts large underground casualty clearing stations had been constructed, each from 8,000 to 12,000 square feet in area, and each proof against a direct hit from high-explosive bombs up to 200 lb. and in many cases up to 500 lb. These hospitals contain about 200 beds each, and are so equipped that they can absorb sixty cases an hour and can supply all facilities for carrying out urgent operations on the wounded even during continuous air raids. Mr. Simmonds, after studying the question in France, Germany, and also under action in Spain, considered that no great surface hospital in a large city in this country would be able to carry on for more than a day or two after the outbreak of war. He added that it was a fantastic proposition to expect medical services to operate with even a fair degree of success in the centre of highly vulnerable and congested areas.

The seriousness of the picture which Mr. Simmonds drew will no doubt come as a surprise to some, but to those who have thought much about the question, and who have had experience of mass bombardment, his conclusions will not seem in any way exaggerated. To have such underground casualty clearing stations ready equipped at all times, situated in easily accessible areas in every district, and with medical and nursing staffs properly allocated, as is the case in Paris, would add very greatly to the sense of security of the civilian population. They would then realize, as did our troops in the last war, that all possible medical precautions were being taken for their safety. These bomb-proof hospitals would enable the medical organizations to give continuous service during incessant air raids, even if surface hospitals were being put out of action one after another.

In addition to the above it is essential that bomb-proof shelters for the civilian population should be provided on a large scale in all towns, for in no other way can the number of probable casualties be kept within manageable limits. If shelters and hospitals were built as we have suggested they would provide for many years to come an excellent insurance against aerial attack, and such a result is worth far more than any expense likely to be incurred in their construction. What has been done in Paris can be done in British cities, and if it is to be done it must be done quickly, for every day is precious.

It is earnestly to be hoped that the full weight of medical opinion will be used to emphasize the immediate importance of these plans.—We are, etc.,

R. OGIER WARD.
CLEMENT FRANCIS.

London, W.1, Dec. 12.

SIR,—While supporting strongly Major W. V. Fawcner-Corbett's suggestion (*Journal*, November 26, p. 1114) of a full staff for medical A.R.P. work, may I protest even

more strongly against his obvious but dangerous suggestion that the nucleus for this staff could be provided by the county and borough officials; and this on many grounds.

First of all, county medical officers are—or should be—already fully occupied with their normal jobs. Only a few months ago a county M.O.H. wrote to me that he was busily engaged on twenty big county schemes, of which, presumably, A.R.P. was one. In such conditions it is inevitable that a large part of the work gets done by others, usually hard-working and well-meaning clerks. The natural result is inefficiency, irritation, and extravagance. It certainly was so with A.R.P. during the crisis, and for some while to come A.R.P. work is large and important enough to demand the whole energies of the best men who can be found for the job. If it is to be efficient it cannot be standardized all over the country, for the requirements of each area differ greatly according to geographical, social, and industrial circumstances.

Secondly, county boundaries are the most curious things in the world, and if an A.R.P. scheme is to be efficiently and economically run it should be grouped according to areas of population and not municipal or county areas.

Thirdly, public health work does not demand nor develop those qualities which are required in emergencies such as air raids are likely to present. Incidentally these are likely to present such urgent and unforeseen problems of pure public health that public health officers will be more than occupied in their own departments, with no time to spare for the actual A.R.P. medical work itself. Though I think it is important that leaders in A.R.P. work should have sympathy and understanding of the problems of public health work, I think it is even more important that they should not be recruited from actual members of the public health services.

Finally, one must try to envisage the condition of affairs at the end of the struggle. If the heads of A.R.P. during wartime are to be existing public health officials, the only outcome I can see is a profession completely absorbed in the Government machine. Whether this should be regarded as a good or a bad thing I do not pretend to discuss here, but the issue is certainly involved in the organization which is to be built up in the next few weeks or months. I sincerely hope that other members of the profession will make known their opinions on the matter, and that the B.M.A. will take some really effective action to see that we do not become enslaved through our patriotic efforts to work in with Government plans.—I am, etc.,

Winsford, Cheshire, Nov. 28.

W. N. LEAK.

SIR,—Surely it has now become quite clear that, if war should occur, life in our big cities will only be possible in bomb-proof dug-outs of the type of the Maginot or Siegfried Lines. This means almost wholesale evacuation, since few people will be prepared to live under such conditions. At present we still talk of evacuation taking place "in the event of war," but presently all will realize that anything like orderly large-scale evacuation of cities when war breaks out would be quite impracticable, and that the evacuation will have to be begun now, while there is at least comparative peace. Further, the idea of billeting will have to be given up. The next war will not be a mere passing phase, but will mean practically the end of our great cities as we now know them. Also, the supply of food from abroad will be largely cut off. If our people are to keep alive at all—I mean such of them as escape destruction in the cities—they will mostly have to be settled on the land and trained to agriculture;

there they will have to raise food, and not primarily for marketing but for the subsistence of themselves, their families, and their neighbours.

It may be said that this is a terrible come-down for civilization. I think, however, that we have here simply a case of the working out of Nature's laws. After all, why should there not be laws of social happenings as well as of physiological and psychological? Apparently our whole hyperurbanized Western civilization has been for a long time increasingly flouting Nature; it has become entirely unnatural, artificial. War, therefore, means the destruction of radically unhealthy tissue, and that is what our great cities have become.

This was what I meant to say when, in another connexion, I raised the problem of "social pathology." Let us face the facts, and in no circumstances fail to take warning from Nature's danger-signal. The rural-urban balance in our civilization has become profoundly upset, and must be straightway redressed or complete disaster will overtake us. Let a well-thought-out and resolute back-to-the-land scheme therefore be entered upon forthwith. And in this good work the medical above all professions should lead, not be led.—I am, etc.,

North Queensferry, Fife, Dec. 5.

A. J. BROCK.

SIR,—The letters in your columns upon air raid precautions, written by men who, as regimental medical officers in war, had a close acquaintance with high explosive and its horrors, deserve a wider publicity than the *Journal*. Unfortunately the British public is lulled to believe that with a multiplicity of gas masks, first-aid lectures, and air raid wardens all is well. They have yet to realize that a yard of efficient bomb-proof shelter is worth more than the ministrations of dozens of doctors to the victim caught in the open by an enemy bomber. Limitation of casualties should be the first objective. Evacuation of population may be impracticable. Underground bomb-proof shelters are essential in all towns.

It would be interesting to know if the present heads of the Home Office and the Ministry of Health have any personal experience of bombardment—the only experience, I think, that can help to visualize a future inferno. Herr Hitler, being in the "forties," has that experience, and is in consequence a true believer in concrete. My friend Dr. F. G. Chandler, as I knew him in 1914, before we both became M.O.s to Highland battalions, was far from being a "yes-man," and I welcomed his letter in the *Journal* of December 3 (p. 1175). He has the courage and perseverance which may yet, in spite of obstruction, get things done. If he fails, then, as bombs fall upon an undefended St. Bartholomew's, he will, I know, be much consoled by the thought that at the House of Commons they have their vaults and underground passages.—I am, etc.,

D. W. PAILTHORPE.

Alresford, Hants, Dec. 6.

Major R.A.M.C. (ret.).

SIR,—There can be no question that if a modern bombing of London ever takes place it will be utterly impossible for students to continue their studies unless there are adequate bomb-proof shelters. These are the urgent requirement. They should be begun and made at once, not after months or years of argument. No other devices are likely to be of such use. Trenches are a good beginning, but not enough. The schemes for evacuating children and others to distant outlying places are more or less futile. Of course, if several days' notice is to be given there may be something in it, but no such notice is expected to be given. Surprise is to be the essence of the attack, and the arrival of bombing planes

is more likely to be a matter of minutes even than of hours, let alone days. In such an event the massing of crowds making for railway stations or other exits would provide just the targets bombers would desire. Therefore urge the authorities to construct bomb-proof shelters at once, either above or below ground. These are by far the most urgently required means of protection for the populace.—I am, etc.,

G. F. ROWCROFT,
Colonel.

Coonoor, S. India, Nov. 30.

The Refugee Problem

SIR,—I should be grateful if you would allow me through your columns to draw the attention of your readers to the special contribution which the Society for the Protection of Science and Learning is making, and has been making over the past five years, to the refugee problem, which the whole of the civilized world is to-day facing with such remarkable spontaneity and generosity.

This Society (of which His Grace the Archbishop of York is president and Sir Frederic Kenyon chairman) exists to help scholars and scientists displaced from their own universities and professions to be reabsorbed into academic life elsewhere, so that their intellectual gifts and training may not be wasted and so that each individual scientist, scholar, and doctor may still be able to make the contribution to knowledge which in many cases he and he alone is capable of making. So far we have succeeded in placing over 500 permanently and nearly 350 temporarily, and among those whom we have been privileged to help are men and women whose intellectual gifts and genius form part of the cultural wealth of the world.

The Society for the Protection of Science and Learning is not concerned at any time with the problem of those practising medical men who seek to come to Britain from countries where they are no longer able to receive patients. Its activities cover only those doctors whose research work has been interrupted in their own land and whose work is of such importance that our Medical Advisory Subcommittee considers that it should be carried on in this country. Needless to say, of very many applications in this class we are, at present, only able to give grants to a small proportion.

The Society is holding a number of meetings early in February in the academic centres throughout the country to enable all those engaged in teaching, learning, and research to give corporate and tangible expression to their sympathy. I hope these meetings will have the most generous possible support, as the latest developments in Germany, the crisis in Czecho-Slovakia, and the new legislation in Italy have trebled our waiting lists and made each individual problem more pressing and acute. As vice-president of the Society I should be grateful if you would publish this letter so that this part of the work undertaken to help these distinguished refugees and exiles of learning may be widely known.—I am, etc.,

6, Gordon Square, W.C.1, Dec. 8.

W. H. BEVERIDGE.

* The Society for the Protection of Science and Learning (formerly the Academic Assistance Council) seeks to help medical research scientists whose work has been interrupted in their own country for reasons of race, religion, or politics. It does not, however, deal at all with practising doctors, as such, who are the care of another committee, presided over by Dr. Robert Hutchison. It considers making grants towards the re-establishment in academic life of medical scientists who

undertake that they will not seek to practise and who are recommended highly by a specially constituted Advisory Subcommittee, as follows: Professor A. V. Hill, Sec. R.S., Professor C. S. Gibson, F.R.S., Professor M. Greenwood, F.R.S., Professor B. A. McSwiney, Professor G. Payling Wright, Dr. George Pickering, Dr. D'Arcy Hart, and Dr. D. N. Nabarro. Among the members of the Society's committee which is seeking to increase the funds available for this work are: Dr. Robert Hutchison, P.R.C.P., Mr. Hugh Lett, P.R.C.S., and Sir Cuthbert Wallace, while Sir Farquhar Buzzard is a member of the Society's Council.—Ed., *B.M.J.*

What is Accredited Milk?

SIR,—I have read the article "Raw and Pasteurized Milk" (November 19, p. 1049), in which you say "examination of the raw milk showed that 30 per cent. of samples contained tubercle bacilli, in spite of the fact that it came mainly from accredited herds." I am interested to note that you suppose that "accredited" herds should produce milk which is freer from tubercle bacilli than milk from non-accredited herds, because the certificate for "accredited" milk is granted purely on the cleanliness of the cowsheds, utensils, and milk itself, but with no tubercle testing of the individual cows or of the milk itself. It must therefore be obvious that the condemnation of "accredited" milk in containing tubercle bacilli should have no connexion, such as is implied in your article, with non-pasteurized milk from tuberculin-tested herds. I maintain that if the test were carried out on such milk, then a very much lower percentage of samples would be found to contain tubercle bacilli; and if this is so your confusion between the terms "accredited" and "tuberculin tested" has created a grossly mistaken impression. I write this as a layman, but as (I hope) an intelligent and progressive milk producer-retailer.—I am, etc.,

Stebbing, near Chelmsford, Nov. 30. Wm. H. CHAPLIN.

* The certificate for "accredited milk" is given not purely on cleanliness but on the veterinary examination of the cows. Under the Milk (Special Designations) Order, 1936, every milch cow belonging to an "accredited" herd must be submitted to an examination by a veterinary surgeon once in every three months, and any animal found to be suffering from a disease that is likely to affect the milk injuriously must be segregated or removed from the herd. The purpose of this injunction is clearly to ensure so far as possible by clinical examination that no cow with tuberculosis or other serious disease of the udder shall be allowed to contribute its milk to that of the herd. If clinical examination is of value in the early detection of udder tuberculosis, as many veterinarians believe, then milk from "accredited" herds should, on the average, be less frequently infected with tubercle bacilli than milk from ordinary herds. The fact that 30 per cent. of milk coming mainly from "accredited" herds was found at Reading to contain tubercle bacilli raises a question as to the efficacy of clinical veterinary examination in protecting the milk supply from tuberculous infection.—Ed., *B.M.J.*

Did Columbus Discover Syphilis?

SIR,—With reference to the annotation in the *Journal* of December 3 (p. 1153), syphilis was no doubt known among the Indians of Peru, under the Incas, before the arrival of the Spaniards. I was employed as medical officer to some isolated mines in Chili, fifty miles from the

coast, from 1882 to 1886, in which period no case of syphilis, congenital or acquired, was brought to me for treatment. Discussing this freedom with reliable men I was informed that Peruvian skulls existed with evidence of syphilitic damage, and, moreover, that the Inca overseers knew that mercury was curative. Sufferers from this disease were sent to work in the cinnabar mines, where this sulphide of mercury dust falling on the bare sweating skin no doubt produced early absorption. The name Chili so closely resembles place names in China that it is reasonable to suggest that the disease might have originated from some sailors on a Chinese junk. Indeed, the slang term for a prostitute was *una Chinita*.—I am, etc.,

Merionethshire, Dec. 5.

ARTHUR GRAYLING.

Medico-Legal

THE CROYDON TYPHOID LAWSUIT

A TEST ACTION

The epidemic of typhoid which broke out in Croydon in the autumn of 1937 caused forty-three deaths and attacked, in all, 341 persons. The findings of the inquiry which was held to investigate the disaster attached a substantial amount of blame to the county borough authority. Many of the persons who suffered made claims against the corporation, and one of these claims was selected by consent as the foundation of a test action, the findings of fact and law in which should, so far as they were applicable, decide the other claims.

The Case of Miss Read

One of the patients was a girl of 15 named Patricia Rosemary Read, and she and her father sued the council for damages sustained through her illness. Her father claimed special damages for the expense of her medical treatment, nursing, and other items, and she claimed general damages for pain, suffering, and inconvenience. The grounds of the action were fourfold: (1) breach of contract for the sale of goods, in which, in accordance with the Sale of Goods Act, 1893, Sect. 14, the corporation had warranted the purity of the water it supplied to a ratepayer; (2) breach of contract to render services, with a similar warranty; (3) breach of its statutory duty under the Waterworks Clauses Act, 1847, Sect. 35, to provide and keep in their pipes a supply of pure and wholesome water sufficient for the domestic use of the inhabitants of the borough; under the Public Health Act, 1936, Sect. 115, to secure that the water which they supplied for domestic purposes was wholesome; and under Sect. 111 of the same Act, to take from time to time the necessary steps to ascertain that its water supplies were sufficient and wholesome; and (4) common law negligence—that is, breach of a duty to use a requisite degree of care or skill in supplying to Mr. Read's house water which the corporation knew that he and the members of his household would drink.

The Addington Well

The hearing took place before Mr. Justice Stable in the middle of last month. A large volume of evidence was called, and brought out substantially the same facts as were elicited at the inquiry.* The corporation were generous in their admission of documents. The system through which the infection was spread is called the "high level" system,

and is fed from the Addington reservoir. This is fed from the Stroud Green well and the Addington well. There was no real doubt that the infection came from the Addington well. This is sunk in the chalk and has a number of adits—horizontal tunnels driven out in various directions near the bottom to collect water from the surrounding earth. It is supplied from a gathering-ground immediately to the south, and this, although it contains a number of possible sources of contamination, was not seriously incriminated. Its nature had, however, this importance in the case: that the risk of contamination from certain places in it, such as cesspools and a pig farm, was serious enough to throw on the corporation a duty of exercising considerable vigilance. The records of the corporation show that the Addington supply had for at least thirty years been under some measure of suspicion, and that the corporation had taken steps to improve the gathering-ground, had installed an ozone plant in 1908, a high-pressure plant and chlorinating plant in 1928, and ammoniating plant in 1936. In 1937 it spent a large sum in acquiring land to protect the gathering-ground. The water is pumped from the well to a high-pressure filtering station, then to the chlorinating plant, then to a filtered-water tank, and then to the Addington reservoir. The surroundings of this reservoir were at one time suspected, but the corporation took appropriate steps to protect the water, and there was no evidence that infection entered at that point.

For a considerable time before the epidemic broke out the water was analysed once a month. Samples were taken both from the well and from the reservoir: the former to show what precautions ought to be taken to make the well-water fit for human consumption, the latter to show whether those precautions had been effective. At the end of September, 1937, the corporation started work on the well. A depression had appeared in the floor of one of the adits and silt had collected; it was therefore desirable to cut a tunnel from this depression to one of the adits at a lower level. While the work was going on the water from the well was pumped to waste, and after the workmen stopped work in the evening about half an hour was allowed for any disturbance to subside and then water was again pumped to supply. This operation was finished on October 16, but another had immediately to be undertaken. One of the two pumps had broken down, and it became necessary to brick up two of the adits in order to prevent the well from receiving more water than the remaining pump could deal with. During this vital period, from October 16 to November 3, the whole of the water was pumped to supply whether the men were working in the well or not.

Eighteen workmen were employed, each of whom had worked for the corporation before, but none had been medically examined. They had been instructed to be careful to use the lavatories provided on the surface immediately before they went down to work. A man who wished to relieve himself was required to come to the surface to do so, but on a few occasions an open bucket was let down to allow a workman to urinate. One workman, who was called throughout the proceedings "Case A," had been in the employment of the corporation since 1921, and had seemed a perfectly fit and proper person to work in close proximity to the water supply. He had, however, suffered in the war from typhoid fever and was a carrier.

The history of the precautions taken by the corporation showed that in May, 1936, the medical officer of health received an analysis of the Addington water which showed the presence of *Bacillus coli*. He formed the opinion that the water was not adequately filtered. The borough engineer pointed out that a chlorinating plant was installed, and that, if the medical officer considered it should be used, that would be done, but he thought that it would be better to avoid using it if possible. On July 18, 1936, the chief water assistant—the officer responsible for water supplies—sent a memorandum to the borough engineer containing these words: "I would like to put on record that I have for the last two months been of the opinion that chlorination should be in regular use in view of the analyses received." This memorandum indicated, as the learned judge pointed out, that despite the apprehension expressed by the medical officer of

* The proceedings at the public inquiry were recorded in the *British Medical Journal* of December 11 and 25, 1937; January 1, 8, 15, and 22, 1938; and the report by Mr. H. L. Murphy, K.C., on February 19.

health in May and the opinion formed by the chief water assistant no steps had been taken to chlorinate the water. On July 20 chlorination was started, but no log of its use was kept. It seemed to have been used as a remedy for a varying impurity in the supplies, and to have been increased when the analyses showed a deterioration, and to meet a sudden emergency such as the death of a workman in the well at the end of 1936. At the end of October, 1936, an analysis showed a great increase of *B. coli*—a report which, incidentally, did not come to the notice of the chief water assistant for a fortnight. On November 13 this officer directed his subordinates to increase the rate of chlorination until further notice. At the end of April, 1937, for no reason that appeared at the trial and presumably by a mere oversight, the practice of taking an analysis of the raw water at the Addington well was abandoned. Neither the chief water assistant, the borough engineer, the water committee, nor anyone else so much as noticed that this precaution had been allowed to drop. On September 17, 1937, a week before the work on the well began, the practice of filtering and chlorinating the water was wholly abandoned, and it was not resumed during the entire time that the workmen were working down the well. On November 1, by which time the authorities knew of the epidemic, heavy chlorination was applied and—a fact which the judge regarded as significant—no more primary cases occurred after November 4.

Attitude of the Corporation

The learned judge drew special attention to what he called the wholly commendable attitude of the corporation towards the action. Instead of adopting a defensive and obstructive position, and leaving the plaintiffs to ferret out and prove as much or as little of the material facts as they could, the corporation made the fullest and most candid admission of all the material facts it could ascertain. When its officers knew that there was an outbreak of typhoid they made every effort to discover the origin and to expose any weakness in the system of administration, regardless of the consequences which their investigation might have for the persons who might be responsible and on whose sense of public duty the success or failure of the investigation largely depended. In making an investigation, which proved to be the instrument which brought the onslaught of the epidemic to a standstill in its very early stages, the officers of the corporation subordinated every consideration of private interest to the paramount necessity of finding out the truth. His Lordship had no doubt that the action of the corporation more than restored any loss of confidence the public might have experienced in its administration of these important health services. Mr. H. J. Wallington, K.C., who appeared for Mr. Read and his daughter, particularly commended the report of the medical officer of health, Dr. O. M. Holden. This, he said, was a very frank account, which sought to conceal nothing. The judge remarked that he was struck by the extraordinary candour which the medical officer seemed to have displayed, and by his disinterested pursuit of the truth, no matter where it led. Counsel agreed that his candour "jumped out of" every line of the report, and said that such considerations made him regret to have to make such a charge against persons of that type.

The Judgment

The hearing of the case occupied eight days, and Mr. Justice Stable reserved his judgment. Delivering it on December 2, he said that the evidence conclusively established that the corporation had been guilty of negligence, not merely of a failure to carry out a duty imposed by statute, but a lack of that care and skill which were to be attributed to a body which had undertaken to supply water to such a community. All the officers were men qualified for their work, and he found no trace anywhere of that degree of negligence which, arising either from indifference, inefficiency, or lack of a sense of responsibility, would amount to a deliberate dereliction of duty. The chief water assistant, who on October 14 had left the service of the Croydon Corporation to enter that of

the Brighton Corporation—just before the end of the first operation on the well and the beginning of the second—was fully qualified and a public servant of integrity, and nothing emerged from the evidence to diminish the confidence which his present employers reposed in him. He was very largely a victim of the imperfect and inadequate system of control in force. On his departure the senior officer directly in charge of the work had given instructions, which he honestly believed to be in accordance with the wishes of higher authority, that on and after October 16 the water should be pumped direct to supply. His Lordship formed a favourable opinion of this officer, but declared that so vital a decision ought not to have been left to a man in his position, and condemned a lack of system under which it could have been taken without at once being brought to the notice of the persons at the head of the chain of responsibility.

Sir Walter Monckton, K.C., who appeared for the defence, had argued that the possibility of the contamination was so remote that no one was to blame for not foreseeing it, and had stressed the danger of wisdom after the event. The learned judge said that in forming his conclusions he had been on his guard to measure the care and skill that were required, not in the light of what was known in October, 1938, but in the light of the experience of the men on the spot in the autumn of 1937. In his judgment the evidence conclusively proved that the epidemic was caused either by an infection brought into the water by the workman who was a carrier of typhoid, or by some unidentified and probably transitory condition in the gathering-ground. The defence had suggested the bare possibility that infection from the excrement of some passer-by had been washed down from the gathering-ground to the well. That this should have happened at the same time as a carrier of typhoid was working in the well extended, he said, the well-nigh limitless possibilities of coincidence almost to infinity. Moreover, whichever had been the origin of the infection, the consequences would have been avoided if proper use had been made of the available protective apparatus.

RESPONSIBILITY FOR WATER SUPPLY

He did not find substance in the criticisms which had been levelled against the sanitary arrangements made for the workmen at the well. He was satisfied that the responsible officers had provided a proper solution of this problem. He found no greater substance in the criticism directed against the absence of a medical examination of the workmen, the method of their selection for the work, and their supervision when at work. With all the wealth of expert testimony which the plaintiffs had at their command, they could only establish a solitary instance, at Caterham in 1879, of an epidemic of typhoid being caused by a carrier. Due care and skill had been taken in the selection of the men, and he was satisfied that the superiors under whose supervision they were working were conscientious, responsible, and trustworthy.

While the probabilities (continued his Lordship), estimated immediately before the outbreak, that the water could be infected by Case A were utterly remote, yet the bacteriologist or water engineer responsible for the supply of water to an urban community must be constantly on his guard against innumerable risks. Though the chance of any one of the risks materializing into a peril was remote, collectively and in the aggregate the danger was real and substantial. In his judgment the corporation had failed in its duty in two major respects. From July, 1936, when the chlorinating plant first came into use, the extent to which this precaution was enforced was haphazard, ill-considered, and inadequate. The decision at the moment of greatest peril, when the water was being put into supply and while the men were working in the well, to omit the customary precaution of filtration and chlorination was, even regarded in the light of what was known then, inexcusable. He would not apportion responsibility among individuals; *prima facie* it must rest on the shoulders of the water committee, to whom was entrusted the general superintendence of the water supply. No evidence had been adduced to show that any one member of that committee made any inquiry or took any step whatever to

formulate any established policy in connexion with chlorination, or to set up machinery to put that policy into effect, or to provide a proper system of supervision and inspection to secure that any policy which was adopted was being efficiently, regularly, and systematically carried out. In these circumstances, where the responsibility *prima facie* rested there he proposed to let it lie.

His Lordship continued: "Sir Walter Monckton further urged, and again with great force, that the policy of chlorination in connexion with chalk wells was of comparatively recent origin and was by no means universally liked. The trouble in this case, in my judgment, largely originated from the fact that on this all-important question there never was a settled policy at all. While I have absolved the corporation and its servants from every charge of negligence brought in connexion with the gathering-ground and the selection and supervision of its workmen, and the conditions under which they worked, these facts cannot be segregated from the other established facts in this case. If some paramount and overriding necessity existed—and I find that there was no such necessity—which demanded that water should be pumped in its crude state straight to supply while work was in progress in the well, then the additional risk to the health of the people of Croydon which was thus inevitably created ought to have been counteracted by additional precautions designed to obviate the possibility of infection being introduced into the water by the close proximity of the workmen. These precautions, which might have taken the form of continual analysis, searching inquiry into the antecedents of the men engaged on the work, and incessant supervision while they were so employed, were not taken. No one made it his duty to inquire whether or not they were taken, or to see that the precautions, if they had been adopted, were observed. The system in this respect proved itself inadequate to support the very heavy burden of responsibility which it had to carry."

THE CORPORATION'S STATUTORY OBLIGATION

On the questions of law involved, the learned judge held that there had been no contract between the corporation and Mr. Read. By the Waterworks Clauses Act, 1847, the corporation, having undertaken to supply water to the inhabitants of the borough, was under a statutory obligation to provide and keep in its pipes a supply of pure and wholesome water sufficient for the domestic use of those inhabitants who fell within a certain category—namely, owners and occupiers of dwelling-houses who had laid the necessary communication pipes and paid or tendered the water rate, and were therefore entitled to demand and receive a sufficient supply. Although rights and obligations under this relationship might be similar to, or identical with, rights created by a contract, the relationship was not a contractual one. Concerning the scope of the statutory duty, he said that Mr. Read fell into the category of persons to whom this duty was owed by the corporation, but his daughter did not.

His Lordship then considered in detail the question of whether or not the duty to provide and keep a supply of pure and wholesome water was an absolute one—that is, whether the corporation could be penalized for breaking it even though they might not have been negligent. After considering many authorities he held that the obligation was limited to the exercise of all reasonable care and skill to ensure that the water was pure and wholesome. He had no doubt that the standard of care and skill in a matter so vital to the public health was a high one, but if that standard was maintained he did not think that the corporation could be held liable for the consequence of some impurity which no care or skill could have prevented. He had, however, found as a fact that the corporation had not used a requisite degree of care and skill.

It had also been argued before him that existence of the statutory duty excluded a duty at common law, and that Miss Read could not recover damages because the corporation owed her no statutory duty. If this view of the law were right, he said, the consequences were startling. The corporation were obliged to supply water sufficient for the domestic needs of ratepayers. This meant a supply sufficient not merely for the ratepayers themselves but also for their families and house-

holds. It must have been within the contemplation of everybody who gave the matter a thought that the water so supplied would be consumed by persons outside the very limited class to which the duty was owed. Miss Read had contracted a dangerous illness as a direct result of the corporation's negligence. In the present case, the judge continued, a complete cause of action could be set out without mentioning the statute at all. If the corporation supplied to Mr. Read's house water for drinking purposes which it knew he and his household would consume, and failed to exercise the requisite degree of skill and care in that operation, with the result that what it supplied was not drinking-water but poison, a person injured would have a complete cause of action at common law for the damage sustained as the result of that negligence. He awarded an agreed sum of special damages to Mr. Read, and £100 general damages to his daughter.

The Corporation and Other Claims

The corporation has announced that it will not appeal against this decision, and it will deal with the 230 or so other claims against it as quickly as possible. The Finance Committee is anxious that proper compensation shall be paid in other cases where the issues are the same as those of the test action. Until the terms of settlement have been agreed no definite estimate can be given of the cost to the rates. The corporation proposes to raise a loan over a period of twenty years. A total cost of £100,000 would represent an increase in the rates of three-farthings in the pound for twenty years.

MENTAL PATIENTS IN AN UNLICENSED HOUSE

For the protection of persons of unsound mind, Parliament laid down in the Lunacy and Mental Treatment Acts, 1890-1930, that no person of unsound mind might be received or detained, or taken charge of for payment, in a house not licensed for the purpose by the Board of Control. Prosecutions for these offences are rare, and a case heard by the Bournemouth magistrates at the end of November* is of special interest.

Dr. X was summoned on three charges: taking charge of a person of unsound mind in an unlicensed house, receiving another person of unsound mind to board and lodge him, and detaining a person of unsound mind, all between September 8 and October 15 of this year. He pleaded not guilty. An officer of the Board of Control said that the house was not licensed and that some time ago the doctor's attention had been called to the provisions of the Lunacy Act. The patients in question were two women and a man. The wife of the man, giving evidence, said he had a stroke in November, 1937, and was admitted to the house in July, 1938, under the care of Dr. X, who agreed to take charge of him at a weekly rate, which she had paid from time to time to Mrs. X. The sister of one of the women patients said that Dr. X came to the house where they were living and took the patient to the home. In paying for her sister's presence there she had made the cheque out to Dr. X. She had learned a few days ago that it was Mrs. X's nursing home. A managing clerk of the solicitors who represented the relatives of the third patient said that from January, 1934, to the end of 1935 payments were made to Dr. X, but from the beginning of 1936 Mrs. X had taken over and all payments since then had been made to her. From then she had known that it was Mrs. X's nursing home. The medical superintendent of the Dorchester County Hospital and the medical superintendent of the Knowle Mental Hospital, Fareham, gave evidence that they had inspected the three patients and found them certifiable as of unsound mind. A police detective said that he had visited the house and that the defendant had said that the patients were not his and had their own doctors.

Mr. James Amphlett, counsel, instructed by Messrs. Le Brasseur and Oakley on behalf of the London and Counties

* Bournemouth Daily Echo, November 25, 1938.

Medical Protection Society, said that the defence maintained that the home did not belong to Dr. X and that he had nothing to do with the patients; moreover, they were not of unsound mind. The defendant, giving evidence, said that in 1932 he had run a private hotel, which was unsuccessful, and after closing it he had had a nervous breakdown. In 1936 he had become a bankrupt and was still undischarged. One of the patients had been sent by a doctor in 1933. She suffered from cerebral thrombosis, and he saw in her not the slightest sign of insanity. In June this year his wife took the house and she and he had both signed the lease, he at the landlord's request. He spent about four months of the year in bed; he practised as a neurologist and his wife ran the nursing home. He had never run it, and to anyone who came to the door he made very plain that he did not run it. If treatment were required for the patients, Mrs. X received instructions from their doctors and not from him. He never saw any sign of insanity in any of the three patients, and they were not of unsound mind. Cross-examined, he said that he was helping his wife to some extent to run the home, but only on the business side.

Mrs. X said she was a fully trained nurse and the proprietress of the home. Her husband was only her adviser. Two general practitioners of Bournemouth both testified that the three patients were not insane. The first practitioner said that one of the women had cerebral thrombosis and he had asked Dr. X to take her into his previous home at Chine Crescent Road, where he had been living in 1933. She was not insane, of unsound mind, or an idiot. He had seen her later in September of this year and found her normal. The home had proved most useful for senile patients who were not certifiable. The second practitioner said that the other woman was not a lunatic, and that the man had been his patient for twenty-six years, during the whole of which period his mental condition had been absolutely sound.

The Bench found all three charges proved and imposed a fine of £15 for each, with £15 costs.

The heading to a paragraph in this column last week (p. 1231) may have given the impression to a casual reader that pentothal was held to be the single cause of the patient's death. The pathological evidence (briefly summarized in the report) indicated two other contributory causes, and the coroner's verdict was "Death from misadventure."

Mr. Justice Croom-Johnson proposed the toast of "Medicine" at a dinner of the Manchester and District Medico-Legal Society on December 8. He is reported in the *Manchester Guardian* to have said that the realm which lay between the punitive and medical treatments of crime had been inadequately explored. He had been struck by the large number of occasions on which he was called upon to punish people when, in fact, they ought to be the subject of clinical examination and medical treatment. He did not wish to be misunderstood. There was abroad a feeling that the criminal should be better treated. In his judgment a danger existed that, by over-sentimental treatment of the criminal, the administration of law and order might be made extremely difficult for those who had the grave task to fulfil. "But we all feel, as we deal with case after case (especially those who come from our large centres of civilization), that a great deal more might be done in examining cases from the medical aspect." Judge Leigh, the president, said that the society had achieved a membership of more than two hundred in two years, and was helping its two constituent bodies to understand each other better.

The issue of the *Journal of Pediatrics* for November is devoted to the memory of Dr. Williams McKim Marriott (1885-1936), professor of research medicine at the University of California Medical School, and contains a bibliography of his writings and his portrait.

Medical Notes in Parliament

In the House of Lords on December 12 the Housing (Financial Provisions) (Scotland) Bill was read a second time.

In the House of Commons second readings were given to the Cancer Bill on December 12 and to the Reorganization of Offices (Scotland) Bill on December 13.

Dr. Walter Elliot dined with the Parliamentary Medical Committee on December 14.

Cancer Bill

In the House of Commons on December 12 Dr. ELLIOT moved the second reading of the Cancer Bill. He said that no one could deny the urgent necessity for some means of bringing adequate facilities for the treatment of cancer within the range of everyone. Although there was an obvious field for increased research into prevention and causation of cancer, in the past years substantial progress in this direction had been made. Records made by surgeons of the histories of the patients on whom they had operated had shown that patients with cancer could be freed from their disease. Radium had been found to have a definite action on cancer cells which led either to their destruction or to some change which facilitated their removal by healthy tissues. X rays had a similar effect. There seemed to be a belief that in certain conditions they produced even better results.

For these forms of treatment to be successful, however, they must be employed when the disease was at an early stage. There must, therefore, be ample facilities for early diagnosis and adequate treatment, both of which were at present lacking in this country. For many other diseases it was easy for patients, no matter in what remote part of the country they lived, to receive modern and adequate treatment, and, as a result, mortality from these diseases had fallen. He was hopeful that the powers which the Bill conferred would in time achieve sensible results with this terrible scourge, but they must be careful not to underrate the size of the problem.

SOME STATISTICS OF CANCER

Cancer had now become the second on the list of fatal diseases in this country. The annual number of deaths from this disease had been steadily mounting, and the total for Great Britain in 1937 was 74,000. Of the total deaths from all causes during the working period of life (15-65), 17 per cent. were due to cancer; nearly half the deaths (48 per cent.) occurred under the age of 65, while about 10,000 occurred under the age of 50, when working or business capacity was at its fullest and when the heads of families were most necessary to their children. The annual death rate for cancer per million of the population in Great Britain was 835 for 1901 and 1,624 in 1937. Thus the rate had nearly doubled in the course of a generation. That increase was in striking contrast to other diseases, where there had been and still was a steady fall, and meant that over 6,000 persons had died of cancer since the King's Speech on November 9.

All other countries which had registration systems manifested an upward trend. While in Great Britain the percentage increase in the death rate between the quinquennial period 1926-30 and the present day was 14 per cent., in Holland the percentage increase for the same period was 9.5 per cent., in Switzerland 3.7 per cent., and in France 3.9 per cent. These countries appeared statistically to have lower rates than our own, but it was impossible, for technical reasons, to be sure that they had less cancer than we had. Among primitive and native races cancer was by no means unknown, and in some of them there were forms of cancer which were more common than among ourselves. It was not possible, of course, to arrive at comparable mortality figures for these peoples.

There had been much discussion and investigation intended to ascertain whether the increasing number of deaths meant a real increase of cancer. The general opinion seemed to be that much of the increase was readily explicable in other ways, such as increased longevity, more accurate diagnosis, and so forth. In cancer of certain of the more accessible organs the

mortality was declining at almost every age—for example, in cancer of the lip, jaw, and skin. It was probable that this decline was due, at all events in part, to the effect of treatment. Some of the decline, on the other hand, was probably due to a lower incidence in these organs. But there was an increasing incidence for some organs. Certain forms of cancer were disappearing altogether. Cancer of the skin caused by undue exposure to x rays was, we might hope, a thing of the past. Other skin cancers due to exposure to tar, mineral oil, soot, etc., were to a large extent preventable, partly by avoidance of exposure, partly by preventive treatment of those conditions of the skin which preceded the actual cancer. It was probable, too, that some of our health services—for dental care, for the treatment of venereal disease, and for maternal care—contributed to prevention of diseased conditions which might progress to cancer.

From various inquiries conducted by the Ministry it had been estimated roughly that there were over 100,000 persons in the United Kingdom suffering from cancer during 1937. Of these about 10 per cent. were affected with the disease in organs for which treatment had not hitherto been practicable. A further 50 per cent. were susceptible at present to treatment by surgery alone, but only if their disease was diagnosed at an early stage. If the cancer had progressed too far for such treatment little could be done for these patients. In this group were included cancers of the stomach and intestine, which, taken as a whole, accounted for the largest number of deaths. There remained about 40,000 patients who suffered from the disease in easily accessible parts of the body. For these patients treatment by surgery, often combined with radiation, or radiation alone, was effective, especially in the early stages of the disease. Even when the disease appeared too far advanced for any treatment designed to be curative a considerable amount of alleviation and occasional cures could be obtained by the expert use of radiation. Moreover, it was not uncommon for "cures," by the usually accepted standard of five years' freedom from symptoms, to result from irradiation of what appeared to be a hopeless case.

"BOGY" OF INCURABILITY

It appeared from such investigations and estimates as the Ministry had been able to make that, under present conditions, only about one-quarter of the patients who could be treated with advantage obtained treatment at centres which were adequately equipped and staffed. He meant by that having expert surgeons, expert radiotherapists, and a sufficiency of radium and deep x-ray apparatus. It was true that not all the remaining patients were susceptible to treatment, but more might become so if facilities were improved. Some of these cases, for example, belonged to the large group of cases of intestinal cancers, in which symptoms were commonly so indefinite that they were neglected until the disease was far advanced. For such cases the problem was not so much the provision of treatment as promotion of that earlier diagnosis which was so vital.

The long waiting lists at most of the voluntary hospitals had two consequences of great importance to the cancer patient. First, there might be delay in initiating treatment, and, secondly, few voluntary hospitals were able to afford bed accommodation for those patients who were beyond hope of cure and whose sufferings could be greatly alleviated by modern treatment.

There was another cause of delay. Many cancer patients applied for treatment only at a stage when treatment was no longer possible. The reason for this appeared too often to be that the patients, realizing they were not well, and fearing that they were suffering from cancer, which they regarded as incurable, delayed seeking advice until the disease was too advanced. For many diseases delay in seeking medical advice was dangerous; for cancer it was deadly. This bogy of incurability was one of the things that the Bill was designed to combat.

LOCAL ORGANIZATION AFTER CONSULTATION

They proposed by means of this Bill to attempt to secure that no one, wherever domiciled, who was suffering or suspected

by his doctor to be suffering from cancer, would be out of easy reach of the best available advice. Further, everyone would be able to obtain admission to an appropriate hospital, whether for further examination or for whatever treatment was best suited to his condition. The Bill provided for the organization by county and county borough councils throughout the country of arrangements for the diagnosis and treatment of cancer. In the London area conditions were not similar to the rest of the country, and the problem to be dealt with was less than elsewhere. The large voluntary hospitals here were in a position to ensure that few patients with cancer could not obtain readily full facilities for adequate treatment, provided the patients attended at an early enough stage of the disease to make it practicable, while the hospitals administered by the London County Council provided themselves extensive facilities for treatment. It had been estimated that out of some 11,000 persons in London suffering from cancer, about 10,000 were now receiving some form of treatment. Similar conditions applied to almost the same degree in some of the larger towns, and a principal object of this Bill was to secure further progress in the parts of the country not so fortunately situated.

The local authorities were required to submit to the Minister schemes showing their arrangements for ensuring that patients should receive whatever treatment was best fitted to their condition. These schemes would be worked out after consultation with the voluntary hospitals and medical practitioners in the area and with the Radium Commission. Additional beds would be needed in some districts, and centres for consultation so conveniently placed as to be available for the whole population. Provision was made for the combination of local authorities in joint committees, on which persons other than members of the local authorities could be co-opted. This should bring in the staffs and boards of voluntary hospitals, and should make it possible for two or more authorities to use one treatment centre. It would also be possible for one local authority to utilize the services, in appropriate instances, of two or more treatment centres.

FINANCE OF THE SCHEME: EXCHEQUER GRANT

This was not a radium Bill; it was a cancer Bill. It aimed at bringing the whole range of treatment, by every means of proved efficacy, within the sphere of every person in the United Kingdom. The proposals would involve the expenditure of money, and would be financed by local and central authorities in conjunction with each other. The additional liabilities imposed on local authorities by the Bill were to be assisted by grants from the Exchequer. This would be done at first by specific grants to each local authority, and later by an addition to the total of the block grant. The expenditure to be taken into account in determining the grant would be the additional expenses incurred by local authorities in excess of those already incurred by them in the year ended March 31, 1938, on the treatment of cancer, and was to be determined to the satisfaction of the Minister in accordance with directions to be given by him after consultation with the appropriate associations of local authorities and, if necessary, with individual local authorities.

It was estimated that the Exchequer contribution when the service was in full operation (which would probably be some five years hence) would amount to approximately £300,000 per annum for England and Wales and £50,000 for Scotland. At a very rough estimate the charge on the Exchequer during the first year of the operation of the scheme would not exceed £70,000.

TREATMENT AND DIAGNOSTIC CENTRES

This estimate was based on the assumption that in order reasonably to meet the more immediate future needs there would be required, first, the equivalent of about twelve new treatment centres in addition to the twenty-two existing treatment centres fully equipped and staffed, with radiotherapeutic departments, at general hospitals geographically distributed over the country. The twenty-two centres were situated at hospitals so placed geographically that there were still large areas of the country for which the proper facilities were not reasonably accessible. Thus, in England and Wales

we had one hospital on the Tyne, three in the West Riding, three in South Lancashire, four in the Midlands, two in the Eastern Counties, one on the Cornwall-Devon border, one in South Wales, one in Hampshire, one on the Severn, and one near London, leaving three principal areas of the country inadequately provided for. These were a horizontal band of country south of the Tyne, between it and the West Riding, North and Mid-Wales, and an oblique band from the Wash to Devon.

The largest of the National Radium Centres were associated with the teaching hospitals of provincial medical schools, and it was hoped that through these channels, as well as others, a larger number of expert radiotherapists would become available to staff the existing centres, when expanded, and the new ones to be formed. It could not be too strongly emphasized that treatment by radiation must be administered by those who had received special training. In inexperienced hands both radium and x rays were dangerous. When radium was first introduced for the treatment of cancer there was not infrequently damage to patients, because the dangers resulting from the inexperienced use of this powerful weapon were not fully realized. The same applied to the use of deep x rays.

Secondly, additional beds, approximately 1,000 in number, would be required at the existing or new centres or in hospitals associated therewith; and, thirdly, about 300 to 350 consultation centres for diagnostic and other purposes.

The estimate of an Exchequer contribution of £500,000 for England and Wales was based on the assumption that the total net additional expenditure of local authorities in England and Wales would be in the region of £600,000—namely, additional beds, £390,000; consultation centres, £350,000; and, say, £30,000 for travelling expenses of patients. This total would be reduced by the amount recovered from patients. This amount was necessarily conjectural, and had been assumed as £170,000, thus giving the net total cost of £660,000 for England and Wales, involving Exchequer grants of £500,000.

PROPOSALS CONCERNING RADIUM

Turning to the provision of radium and other radiotherapeutic substances, Dr. Elliot said that in this matter they proposed to work through the two existing organizations—the National Radium Trust and the Radium Commission. These bodies were constituted by Royal Charter in 1929, the Trust to acquire and hold radium and the Commission to manage its distribution. The Trust owned about 20 grammes of radium, which it bought out of funds provided partly by public subscription and partly out of a grant of £100,000 from the Exchequer. It had also about 18 grammes on loan with an option to purchase at £4,500 a gramme, including containers. This radium could not be retained indefinitely on loan; and if it was to be kept for use here the Trust must be put in a position to pay for it. The radium managed by the Commission was at present distributed mainly in the twenty-two radium centres already referred to. Clause 3 of the Bill provided that the Minister might, from moneys voted by Parliament, lend the Trust up to a maximum of £500,000 to enable it to buy radium and other radio-active substances and apparatus and appliances for radiotherapeutic treatment. Obviously the first charge on this fund would be the money to enable the Trust to pay for the 18 grammes which it had on loan. But more radium would be required for the purposes of the Bill, and when the Government decided on its introduction it authorized the Trust to negotiate for further supplies before its decision was made public. The Trust had accordingly secured an option to buy a further 10 grammes a year for the next five years at a price of £4,500 a gramme, this not including containers. The Trust was, however, not pledged to buy more than 2 grammes a year (10 grammes in all), so that the new actual commitment amounted to not more than about £50,000, and the Trust had an option which, if it exercised it, would involve an expenditure of another £200,000. If the price of radium fell, the Trust would be able to take advantage of the lower price except in regard to the 10 grammes mentioned, and it could,

of course, accept tenders from other companies if the price was satisfactory.

The radiotherapeutic treatment of cancer included the use of deep x rays as well as radium. Experiment in the technique of this form of treatment was constantly proceeding—for example, recent experiments with a voltage of 1 million. Also, the recent invention of the cyclotron had opened up possibilities of new developments. It was desirable that the financial resources and the services of the Trust should be available in respect of these other forms of radiotherapeutic treatment. To enable it to carry out these new functions effectively consideration was being given to the revision of its Royal Charter: (1) so as to authorize it to acquire and hold other substances and appliances for radiotherapy, in addition to radium; and (2) to provide for any desirable alterations in the personnel of the Trust and Commission.

PROHIBITION OF MISLEADING ADVERTISEMENTS

Clause 4 of the Bill prohibited the publication of misleading advertisements offering treatment and cures for cancer. These advertisements were not accepted now by the two great newspaper organizations (the Newspaper Proprietors' Association and the Newspaper Society), both of which had informed him that they supported the inclusion of this clause. Many of the so-called cures for cancer which had from time to time been offered to the public were in themselves harmful; their danger was that of inducing the sufferer to postpone proper treatment until it was too late. The Bill accordingly prohibited the circulation of these advertisements to the lay public, while placing no difficulties in the way of bona fide announcements made to the medical, nursing, and pharmaceutical professions, whether in respect of the methods of treatment already referred to as being effective or of other methods which might be discovered in the future.

There would, he thought, be no objection to the main purpose of the Bill. It had, however, been suggested that the weighting of the population which was adopted for block grant purposes was unsuitable for the present service. On that it might be said that the weighting was designed to give effect to the relative needs of various authorities in relation to their expenditure as a whole, and that any question of the suitability of the weighting factor was not appropriate to the present Bill. This basis of distribution was reviewed less than two years ago, accepted by the associations of local authorities, and again confirmed by Parliament.

On the technical side it had been suggested that the Bill provided for too great an expenditure upon radium. It would be realized that there was a difference between the world-wide attack on causes that science everywhere was making and this national attack on the disease itself by means of diagnosis and treatment. Great Britain played a prominent part in research, carried on either under the aegis of such organized bodies as the Imperial Cancer Research Fund directed by the Royal Colleges of Physicians and Surgeons, the British Empire Cancer Campaign controlled by a group of distinguished lay and medical persons, or by specialized institutes and organizations such as those of the Royal Cancer, Middlesex, St. Bartholomew's, London, Leeds, Edinburgh, and other hospitals or by individual workers. He had already received an assurance from the Imperial Cancer Research Fund and the British Empire Cancer Campaign that they would continue to do their utmost, and he was sure this would apply equally to the other voluntary organizations he had mentioned. He need not remind the House also of the most valuable research which had been carried on for many years by the Medical Research Council, with the help of moneys provided by Parliament. This indispensable work would, of course, be continued and developed quite independently of the present Bill.

DEEP X-RAY THERAPY AND THE CYCLOTRON

Mr. J. D. COOKE said that up to the present the cause of cancer had not been discovered. It was, nevertheless, quite certain that by a combination of methods many patients were being cured to-day. Emphasizing that early diagnosis was the most important thing, he said that there was no surgeon

who did not recognize that radium, x rays, and surgery were much less important than the fact of getting the cases known. A greater number of patients could be cured if they could arrive at an earlier diagnosis and give earlier treatment. There was no question about the importance of the educational factor, but there were many difficulties to overcome. It was very necessary that, in giving information about the disease and the necessity for early treatment, they should avoid creating a form of cancer neurosis. All medical men knew that although cancer was a very serious disease, the fear of cancer was almost as bad, and it would not be easy to conduct an effective educational campaign unless they recognized and dealt with this difficulty. These difficulties could be got over by stressing the great improvements in scientific treatment and the fact that a very large number of patients could be cured—and without operation, which was a thing that people objected to—if only they would take steps to have the condition diagnosed and treated. Publicity in the Press would be a great help; and in several ways possibly the B.B.C., by means of scientific health talks in which this particular matter could be gently and delicately introduced, could render assistance.

The next important thing was that there should be readily available for the patient for early treatment the resources of the hospitals—the surgeon, the radiologist, the expert in radium, and the nursing staffs. It was quite wrong to suggest that there need be any fear of this team of experts. He did not think it would be possible under the Bill to give all the increased educational facilities needed for training people. It was vital that every opportunity should be taken to give the fullest scope for further education in this direction, because x rays and radium were most dangerous weapons. It was most important that this Bill should not be regarded as a radium Bill. In recent months, perhaps years, the value of deep x-ray therapy, compared with radium therapy, had been increasingly appreciated. The former had certain advantages: it was much less expensive, it could be applied with a greater degree of safety, it had a deeper penetration, and it could be made more regionally available all over the country. More especially in superficial cases it was more effective than radium.

The Bill would certainly increase the opportunity for therapeutic research. Every bed made available for the treatment of cancer was a source of therapeutic research. There was great scope for work at the present time in deciding whether deep x-ray therapy was superior to radium treatment. There was also an instrument in use called the cyclotron, which was invented in the United States. He did not understand it himself, but it produced what were called neutrons, which were said to have a penetrating power five times as great as radium and deep x rays. There were, he understood, only two of these instruments in the country to-day—one at Liverpool and one at Cambridge. He mentioned these things to emphasize the fact that scientific progress was constant and progressive, and although at the moment there might be a suggestion that £500,000 should be spent on radium, they must contemplate the possibility that within a year or two something much more important and effective would be available. It was most important that the research and the funds should be made available not only for radium but for any other treatment that might be equally or possibly more effective.

A most important thing in regard to hospital work was the follow-up observation treatment. The Minister had made an important provision by arranging that the travelling expenses of the patients and the friends who accompanied them might be paid. Otherwise, there might be a tendency on the part of persons who could not afford the expense to neglect the second, third, fourth, and even fifth visits which ought to be made to the hospital. On the whole the Bill would prove magnificent in its effects.

PLANS FOR SCOTLAND

Mr. WEDDERBURN said that the need to make modern facilities for diagnosis and treatment of cancer available was no less in Scotland than in England. Deaths from cancer

in Scotland numbered 7,810 in 1937, as against 3,635 deaths from all forms of tuberculosis. It was estimated that the number of diagnosed cases of cancer in Scotland to-day exceeded 12,000. There were four Scottish centres approved by the Radium Commission—at Glasgow (2), Edinburgh, and Aberdeen. Extension of the cancer service in Scotland might be based on the existing national radium centres, with the addition of perhaps one other. From these centres a service would be regionally organized to cover the whole of the country. Within each region there would be subsidiary hospital centres (generally in large towns) where consultative sessions would be conducted by experts from the parent centre, who would also supervise such treatment as could be carried out at some of the local centres and refer to the parent centre cases that required highly specialized resources. These local consultation centres would be useful also for follow-up work. It was estimated that the additional provision necessary for the early treatment of cancer in Scotland should provide for about 6,000 patients a year. Assuming that each cancer bed if fully utilized would deal with about twenty cases a year, a total of not less than 300 beds would probably suffice. This would involve the provision of perhaps from 150 to 200 new beds. It was proposed to set up a small advisory committee in Scotland composed of persons having the necessary experience of local government and of treatment requirements to review existing facilities for cancer treatment and the possibility of expansion of these, and to make recommendations on the extent to which it appeared desirable that local authorities should act together in making arrangements for the cancer service.

MEDICAL OPINION: "A RADIUM BILL"

Dr. SUMMERSKILL thought the Bill would make some small contribution to combating cancer, but it should be called a Radium Bill; it was not in the slightest respect a comprehensive Cancer Bill. The Minister was over-optimistic in saying that the cancer centres would be adequately staffed in five years; she would put it at, perhaps, fifteen years. The Bill said nothing about finance for research. The lower they got in the economic scale the more sharply the cancer death rate rose, and the poor were not being treated in the first stages. The only long-term solution of the problem was to introduce a State medical service in the country.

Sir ERNEST GRAHAM-LITTLE said that the Minister of Health should have consulted the experts who had knowledge and experience behind them. The Minister was mistaken, no doubt genuinely, in thinking that the Bill would not be regarded as a Radium Bill. He (Sir E. Graham-Little) had found consternation in the ranks of those who practised these special subjects. They said that the net result of the Bill was to impress on the public that there was nothing but radium for the treatment of cancer. Unfortunately the Minister had not overtaken the actual therapeutic position of the treatment of cancer. Radium was really a receding force rather than an advancing one. It was not nearly as safe as some other treatment, and required the most expert and special knowledge.

Emphasizing the extreme difficulty of early diagnosis of cancer, he pointed out that it was the general practitioner who saw the early cases. Unfortunately, the general practitioner was not in love with the Bill. It became even more necessary here than in any other department of medicine that the general practitioner should be more able to recognize the disease. He was voicing a considerable section of specialist opinion when he said that the scheme for the arrangement of the centres entirely through the local authorities was very suspect. In London the voluntary hospitals would be distinctly uncomfortable at the idea that they had to apply to the London County Council for any help under this scheme.

Pleading for more research, he said that one view was that the cause of cancer was an ultra-microscopic virus. Surely the obvious remedy for that was to experiment with better microscopes. With microscopes of greater power the prospect was very strong of being able to find the actual causes of many diseases which at present were rather glibly described as ultra-microscopic. It was in that direction that money should be freely spent. Provision for this, which was much

the most important part of the cancer problem, had been scandalously under-estimated in the scheme.

Sir HENRY MORRIS-JONES urged that general practitioners should be in a position to send any case of which they were in doubt to a hospital, not only for treatment but for investigation. Unless facilities for investigation were coupled with those for treatment there was a danger that the Bill would be weak in this aspect of dealing with the problem. The Minister had made ample provision in the Bill to enable him to consult all those involved, both lay and professional, in such a way that the best advice was secured for the interests of those suffering from cancer. He welcomed the Bill, which was in the right direction.

THE GENERAL PRACTITIONER AND THE SCHEME

Sir FRANCIS FREMANTLE said the Minister, to a certain extent, had himself to blame for the fact that there had been such an outcry that the Bill had been produced as if it were a Radium Bill. Although it was called a Cancer Bill, it was recognized everywhere that the reason for the secrecy was the proposed purchase of, or the option to purchase, radium. Therefore that seemed to be the centre of the proposal in the Bill. The lines on which the Minister now recommended the Bill to the House were laid down in a memorandum on the provision of radiotherapeutic departments in general hospitals, issued by the Ministry of Health in March. One paragraph of that memorandum stated that "the effective treatment of cancer now demands the partnership of three highly specialized forms of therapy—surgery, radium, and x rays." In a report of the Medical Research Council, of which he (Sir Francis Fremantle) had an advance copy, there were summarized the reports from all the research centres, and there was a table showing the relative frequency of surgical and radiological treatment in the research centres. By surgical treatment alone 27 per cent. of the cases had been treated; by radiation alone, 31 per cent.; and by x rays alone, 23 per cent. That showed that in the research centres and hospitals the figures were fairly easy as between the three different methods of treatment. That was a reason why the Bill should not be called a Radium Bill, but a Bill for the treatment of cancer in the best up-to-date way.

The general practitioners were the persons to whom people went when they had something wrong with them. Was the Ministry of Health consulting the organizations which represented the general practitioners? It might be that the Ministry was doing that, but he asked for an assurance that the British Medical Association would be consulted, if they had not already been consulted, concerning the terms in which the scheme was to be worked out. The general practitioners ought to be brought into the scheme from the beginning, because it was on them that we must depend. More and more research was needed. One of the greatest things the Minister could do would be to see that provision was made for the proper training of medical men in the latest methods of radium and x-ray treatment. It would be possible and wise to set aside some particular place and to build up a school for training these people.

GOVERNMENT REPLY

Mr. BERNAYS, replying to the debate, said it was certainly not the Ministry's intention to press radium on the medical profession. There was no intention in any way to stereotype the method of the treatment of cancer. That was a question for the specialist. If the Minister had announced the introduction of the Bill before he was ready it would have sent up the price of radium. Therefore it was not possible to have prior consultations. What mattered most was the consultations about arrangements which would be made under the Bill, and he gave the fullest assurance that the Minister would keep in the closest touch with the medical profession and those skilled in the newest methods of remedy. The Minister would be willing to consider a conference with expert members of the medical profession if a desire for it were expressed by all the interests concerned.

The Bill was read a second time, and committed to a Committee of the whole House.

Obituary

The death of Emeritus Professor H. C. J. GRAM on November 14 recalls that method of staining with which his name has been identified among many generations of bacteriologists. He was born in 1853, the son of a professor of law. It was as early as 1884 that he described his method of staining, and it was a source of considerable amusement to him that thenceforth he should be best known to the medical world outside Denmark by this reaction. His first scientific publications dealt with the number and size of the blood corpuscles. He was, however, interested in clinical problems, and one of his studies in this field concerned the clinical reactions of theobromine. In 1891 he was appointed professor of pharmacology, and in the following year he assumed the duties of senior physician to the Frederik Hospital, Copenhagen. In 1900 he was appointed a professor of medicine, and he did not retire from his hospital and professional appointments till 1923.

An obituary notice of Dr. N. D. BARDSWELL appeared in our last issue at page 1234. The following cable from the Governor of Cyprus has been received by the National Association for the Prevention of Tuberculosis: "I have learnt of Dr. Bardswell's death with deep regret, which will be shared by all classes in Cyprus, where his work and visits have entirely changed public attitude towards tuberculosis in a manner which is of greatest assistance to Government in its campaign against the disease. I should be grateful if sincere condolences could be conveyed to Mrs. Bardswell."

Correction.—In the memoir of Professor W. McDougall published last week the word "uncriticizability" was by inadvertence printed "uncriticized ability."

Universities and Colleges

UNIVERSITY OF BRISTOL

C. H. G. Price has been approved at the examination for the degree of M.D.

UNIVERSITY OF SHEFFIELD

At its meeting on December 9 the University Council received the resignations of Dr. Arthur Pool of the post of lecturer in mental diseases and of Mr. A. W. Fawcett of the post of lecturer in surgical pathology. The Council accepted the resignations with regret and thanked Dr. Pool and Mr. Fawcett for their services to the University.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates for the degrees of M.B., B.Ch. have satisfied the examiners at the examination indicated:

SURGERY.—G. C. D. Evans, R. Tiplle.

NATIONAL UNIVERSITY OF IRELAND

The honorary degree of LL.D. was conferred on Sir Walter Langdon-Brown, Emeritus Professor of Physic in the University of Cambridge, at University College, Dublin, on December 8.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary meeting of the Council was held on December 8, with the President, Mr. Hugh Lett, in the chair.

Mr. Seymour Barling was appointed to represent the College on the Court of Governors of Birmingham University, and Mr. L. E. C. Norbury on the Central Council for District Nursing.

It was decided that the following words should be added in parentheses between paragraphs 15 (b) and 15 (c) of the regulations for the Fellowship:

"Provided that the candidate has dissected the entire cadaver, the study of dissected parts either in the dissecting room or in the museum may be included in the sixty weeks."

Diplomas

Diplomas of Fellowship were granted to the following thirty-nine candidates:

G. Mael, Housden, M. Gordon, H. J. Croot, D. M. Cooper, I. N. Blusger, R. Sampson Handley, I. H. Griffiths, Margaret M. C. Loudon, B. W. Fickling, E. P. H. Drake, S. R. Chandra, H. R. S. Harley, S. Marinker, V. D. Logue, H. S. Kander, E. H. Hambly, J. K. Bremer, E. S. James, E. A. E. Hedberg, L. Chanock, N. R. Desai, A. W. Douglas, E. E. Dunlop, H. H. Eddy, N. Garber, W. B. Highet, T. G. Lowden, R. I. Mahadevan, Mary H. Mayeur, K. Mazhar, F. H. Mills, A. L. Newson, H. R. C. Norman, J. G. O'Donoghue, R. Orgias, H. Park, E. P. Row, H. Sobhi, G. M. Thomson.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following seventeen candidates:

J. N. Abelsohn, P. T. Ashby, C. J. Bashall, A. K. Boyle, J. T. H. Butt, W. A. Cobb, T. Dinsdale, Margaret B. Dow, P. G. L. Essex-Lopresti, N. R. James, D. C. R. R. Jenkins, A. Leitch, A. D. Morgan, O. N. Roussel, R. Shaw, A. J. Smith, Una M. Westell.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on December 5, with Dr. John Henderson, president, in the chair, the following were admitted Fellows of Faculty under Chapter III of the regulations:

Duncan McCallum Blair, M.B., Ch.B., D.Sc., John William McNec, M.D., F.R.C.P.

The following were admitted Fellows of Faculty under Chapter II of the regulations:

Prem Datta Bhargava, M.B., B.S., D.T.M. and H., Hugh Cameron McLaren, M.B., Ch.B., Nau Nihal Singh, M.B., B.S., D.T.M., Thomas Ferguson Stewart, M.B., Ch.B., John Wilson, M.B., Ch.B.

Medical News

The House of the British Medical Association, including the Library, will be closed for the Christmas holiday from 5 p.m. on Friday, December 23, to 9 a.m. on Wednesday, December 28 (Library 10 a.m.). Owing to the holiday the *Journal* for December 24 will go to press on Tuesday, December 20, and all editorial communications and advertisements intended for that issue should reach the Editor and Advertisement Manager respectively by the first post on Monday, December 19, at the latest. Material for the issue of December 31 should reach the Editor or Advertisement Manager by the first post on Friday, December 23.

A meeting of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square, W.C., on December 21, at 5.30 p.m., when papers will be read by Mr. J. Smiles on "The Application of Annular Oblique Incident Illumination to the Study of Normal and Infected Chorio-allantoic Membrane" and Mr. N. Ingram Hendey on "Some New Species of Diatoms."

The issue of *La Riforma Medica* for October 8 contains an illustrated account of the eleventh International Congress of Surgery, held at Brussels from September 19 to 22, by Professor D. Giordano of Venice.

Dr. Joseph Hoguet has been appointed medical director of the New York World's Fair of 1939. The medical exhibits are to illustrate the progress of medicine and of public health and the anatomy of man.

The King has appointed Dr. Edgar Cochrane to be a Member of the Executive Council of the Island of Grenada.

On November 19, his seventieth birthday, Dr. Thomas S. Cullen, professor of gynaecology at Johns Hopkins University, was given a dinner at Baltimore.

The German Chancellor has recently awarded the German Red Cross distinction of the first class to the French physicians, Professor Baumgartner and Dr. Paul, for their treatment of Herr vom Rath, the assassinated Counsellor of the German Embassy in Paris.

EPIDEMIOLOGICAL NOTES

Acute Poliomyelitis

There was a slight decrease in the incidence of acute poliomyelitis in England and Wales during the week—37 (39 in the week before)—but in London the figures rose from 7 to 9 in the week under review. The chief counties affected were: London 9 (Wandsworth 3, Battersea, Deptford, Hackney, Lewisham, Stepney, Woolwich 1 each); Gloucestershire 4 (Bristol 4); Southampton 4 (Bournemouth 2, Southampton and Romsey 1 each); Essex 3 (Colchester, Hornchurch, and Ilford 1 each); Leicestershire 3 (Leicester 3). Of the 2 cases of acute poliomyelitis notified in Scotland 1 each occurred in Ayr County and Kirkcaldy.

Enteric Fever

Notifications of enteric fever in England and Wales rose in the week under review from 21 to 29, while in London they fell from 9 to 8. The chief centres affected were: London 8 (Islington and Shoreditch 2 each, Lambeth, St. Pancras, Stepney, Westminster 1 each); Durham 4 (Sunderland 3, Ryton 1); Essex 4 (West Ham 2, Hornchurch and Thurrock 1 each); Kent 3 (Dartford, Folkestone, and Penge 1 each). Another case of typhoid fever was notified at Shoreditch on Saturday, December 10, making a total at the time of going to press of 26 confirmed cases in the borough and 5 outside the borough, which are probably related to the outbreak. A second death from typhoid fever was reported in Shoreditch on Friday, December 9.

The Registrar-General's Statistical Review for 1937

In the middle of 1937 the estimated population of England and Wales was 41,031,000—19,705,000 males and 21,326,000 females. A birth-rate of 14.9 per thousand persons living was recorded; this rate was 0.1 above that for 1936, 0.2 above that for 1935, and 0.5 above that for 1933, which was the lowest ever recorded. The highest rates were recorded in Staffordshire (17.4) and Durham (17.1), and the lowest rates in Cardiganshire (11.4) and East Sussex (12.0). The death-rate for the year was 12.4 per thousand persons living; 0.3 above that for 1936 and 0.7 above the rate for 1935; it is the highest rate recorded since 1922 with the exception of that for 1929, when the rate was 13.4. When allowance is made for the fact that the average age is increasing every year the resulting corrected death-rate was 9.3, or 0.1 above that for 1936 and 0.3 above that for 1935, the lowest on record. Over a hundred years the average death-rate was 5.1 at ages 5 to 10 years, 3.0 at ages 10 to 15, and 274.1 for people of 86 years and over.

Deaths from all causes in 1937 were 260,057 males and 249,517 females. Infectious and parasitic diseases accounted for a total of 57,996 deaths, compared with 47,769 in 1936, the lowest on record. At 1.41 per thousand the specific mortality from infectious diseases represented an increase of 0.24 per thousand on that of the previous year. The increase was due mainly to the influenza epidemic in the first quarter of the year, when 8,991 males and 9,644 females died from that disease, compared with 3,176 and 2,881 respectively in the previous year. The measles death-rate per million children under 15 years of age, which up to twenty years ago was seldom below 1,000, reached the low record of 114. The scarlet fever death-rate (31 per million under 15) was the lowest recorded, and the whooping-cough death-rate of 195 was the lowest except in 1935, when the rate was 170. There were 152 deaths from infantile paralysis, compared with 102 in the previous year, while the number of deaths from food poisoning (22 males and 15 females) is the highest in the eleven years in which records are given. A decrease was recorded in the mortality of women due to the accidents of child-birth; a rate of 0.94 from septic causes and 2.19 from other causes per thousand live and stillbirths was recorded, compared with rates of 1.34 and 2.31 respectively in 1936. The mortality of infants under 1 year was 58 per thousand live births and was 1 per thousand greater than that for 1935, the lowest on record.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 3, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great-towns (125 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week.) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.
† Deaths from puerperal sepsis.

‡ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Medical Apparatus in 1816

Dr. I. E. McCracken (Newcastle-on-Tyne) writes: I cannot help Dr. Collins (*Journal*, November 12, p. 1028) in regard to part (1) of his query, but I can give him a reference to the term "suspended animation" in part (2). In the annual reports for the period he refers to of the Newcastle-on-Tyne Dispensary the term "suspended animation" is used often, and refers to attempts made to recover persons who apparently were dead from drowning. The committee of the dispensary instigated the development of centres on the banks of the river, where boatmen and others received instruction in methods of artificial respiration. I do not recall the mention of any particular apparatus being used for this purpose.

Condensation Water from Theatre Skylight

Dr. LEONARD P. LOCKHART (Beeston, Notts), in reply to Dr. E. S. Hemsted (December 3, p. 1188), writes: The following is a method successfully employed by me for over ten years. Run a copper gutter at the drip point with a tubular drain through the woodwork, and don't let painters ever block up the outflow. This guttering and drain need periodic cleaning.

LETTERS, NOTES, ETC.

The Problem of the Female Inebriate

Dr. COURTENAY C. WEEKS (33, Bedford Place, W.C.1) writes: From time to time medical practitioners are faced with the problem of what to do with female inebriates whose financial position prevents them from being sent to the more expensive nursing homes. May I bring to their notice the excellent shelter home run by the C.E.T.S. and the Women's Union at Highbury, London, N.5. I can vouch for the home and for the care with which the inmates are treated. Full particulars may be obtained from Miss F. E. Relf, Women's Union, 27, Gordon Square, London, W.C.1.

Contraindication to Sulphanilamide Therapy

Dr. E. IVINY PUDDY (King's Lynn) writes: In view of the statement that "no ill effect has been known to occur to babies whose mothers are receiving this [sulphanilamide] therapeutic remedy," made by Dr. V. E. Lloyd in the October number of the *Journal of Clinical Research*, may I report the following exception. A primipara, aged 23, was delivered by forceps on April 29; the perineum was sutured. Puerperal pyrexia followed. On May 5 I pre-

scribed one 7½-grain tablet of prontosil album three times a day. The infant, which was breast-fed, had had icterus neonatorum but was steadily improving, and the skin was only a pale lemon colour. On May 7 the infant had become an orange colour and the prontosil was stopped forthwith in view of this sudden worsening of the jaundice. By May 14 the infant had recovered. Since this occurrence I have regarded icterus neonatorum in a breast-fed infant as a contraindication to the administration of prontosil to the mother.

Infections of the Hands and Fingers

Mr. J. L. AYMARD writes: The tribute you paid to the late distinguished surgeon Sir David Wilkie by publishing his valuable article upon the above subject in your issue of December 3 leads me to say that, though we differed on some minor points, upon the main issue of lymphatic control we were thoroughly agreed. Only one point, which must be of great interest to those who have read and studied the reference to upper arm control by an elastic band and the figure reproduced on page 1127, I will supplement by quoting from a letter he wrote to me on July 23. "It may very well prove that elastoplast is equally good or better than an elastic bandage to produce mild venous and lymph stasis in a limb. However carried out there can be no question of its value in acute infections." My attempt to expose Bier's congestion as a myth handed down will be found in a book, *The Foment Danger, Wound Infection and its Treatment by Lymphatic Control and Elastoplast*, just published by Messrs. Cornish Bros., New Street, Birmingham.

Thimble for the Surgeon

Dr. F. ALLEN (Nagpur, India) writes: In the *Journal* of October 15 (p. 789) there appears a note by Dr. T. E. Coulson on the use of a thimble. I should like to point out that I was taught this method years ago by Sir William de Courcy Wheeler, and I believe it is mentioned in his book on operative surgery.

Infra-red Rays

"G.P." writes: Perhaps more attention should be paid to the treatment of neuritis and neuralgic pains by infra-red rays. I have had neuritis of the arm for two years or more, and sometimes the pain has been very acute and has lasted for hours. Treatment by drugs, such as salicylates, quinine, arsenic, and iron, proved quite valueless. I set up an infra-red lamp and started treatment five days ago. The pain has entirely gone, though it is too early to say it will not recur. I might point out that it is not necessary to undress to apply the rays; the removal of thick clothing, such as the coat, is all that is required.

Medical Postage Stamps

The eagerly awaited Curie stamp has reached us from France, horizontal in shape, blue-grey in colour, 1 franc 75 centimes plus 50 centimes in value, and bearing the legends "Pierre et Marie Curie découvrent le radium Nov. 1898" and "Union Internationale contre le Cancer." Though the expressions are pleasing enough, the design is overcrowded and unbalanced. A similar stamp has also been released by each of the twenty-one French colonies, lighter in colour and with a slightly different inscription. Soviet Russia has recently issued a set of seven child welfare stamps, all of which are horizontals except the 15 copecks (upright). On the 10 deep green a young mother watches her baby being weighed at a maternity station. The 15 blue-green depicts children receiving a history lesson around Lenin's statue in Leningrad. On the 20 violet-brown and the 40 light brown children are seen looking through microscopes. The 30 red-brown figures boys at a Crimcan pioneer youth camp, and on the 50 deep blue and the 80 light green children are portrayed playing with mechanical toys built by themselves. While the designs are interesting and even striking, artistically they cannot compare with some of the previous issues.

Corrigendum

In a summary of a paper which Dr. Francis Braid read at the annual meeting of the British Orthopaedic Association (*Journal*, December 10, p. 1222) "secondary to cirrhosis of the liver (present in both patients)" should have read thus: "dysfunction of the liver, evidence of which was present in one of the patients."

Pathology of Vitamin C Deficiency. G. Dallhoff—p. 1376.

Nausea and Vomiting of Pregnancy.—Allergic sensitivity to the secretion of her own corpus luteum of pregnancy is regarded by Finch as the aetiological factor in nausea and vomiting in the early months of pregnancy. In a series of cases he obtained a cutaneous reaction following the injection subcutaneously of 0.02 to 0.03 c.c.m. of progestin, directly proportional to the severity of the symptoms. Negative reactions were obtained in patients who had no symptoms. Allergic desensitization by the subcutaneous injection of corpus luteum extract and progestin relieved the symptoms in the former group. Intradermal testing with progestin may determine even before pregnancy whether a patient will or will not be affected. A high proportion of patients with pregnancy sickness had other allergic conditions or gave a family history of allergy.

Results of Investigation of 7,000 Applicants for "Marriage Loan." Felberth—p. 1446.

Applicants for Marriage Loans.—Investigation of 7,000 applicants for "marriage loans" showed that only 4.6 per cent. were unsuitable for marriage, mainly on account of debility and mental deficiency. The incidence of syphilis and gonorrhoea was remarkably small. Of the spinster applicants 24 to 31 per cent. and of the divorced or widowed women 30 to 53 per cent. were pregnant at the time of the application. The mortality among the illegitimate children was much higher than that of the legitimate offspring. The average age of the men was 27 years, of the women 24.6. Most of the applicants belonged to the artisan and working classes.

Complementary Feeding of Suckling Infant. A. E. Russell and T. McKee—p. 832.
Fetido-vasectomy. R. H. Boyd—p. 833.

Thyroidectomy for Cardiac Pain.—Thyroidectomy was done in twelve carefully selected cases of angina of effort, unsuccessfully treated otherwise. There were no operative deaths and but three failures. Methods of case selection and the operative technique are described.

Medical Journal of Australia

Sydney vol. 2 September 3, 1938

- Factors in Prognosis of Cardiac Disease. A. Holmes & Court—p. 361.
Some Observations upon Examination of Men Exposed to Lead Hazard, Including Original Method for Examination of Blood for Polychromasia. L. Windsor-McLean—p. 367.
Endemic Typhus in North Queensland. R. Mathew—p. 371.
Mantoux Test: Single Injection Method. D. Anderson and C. Harvey—p. 378.
Pathological Reports from Children's Hospital, Melbourne. R. Webster—p. 381.
Case of Calcified Cerebral Tumour. E. Robertson—p. 383.
Case of Arterial Angioma of Spinal Cord. E. Robertson—p. 384.
Case of Cerebral Adhesions. L. Snow—p. 385.

Single Injection Mantoux Test.—Tuberculin P.P.D. is a purified protein derivative of tuberculin. It is a solid of constant and low molecular weight, non-sensitizing on repeated injection, unable to produce focal reactions, indefinitely stable, and highly potent in the production of the skin reactions in infected animals. Anderson and Harvey find that a single injection of 1/40 c.c.m. detects nearly all reactors to the orthodox dose of tuberculin with a minimum of sharp reactions.

Medizinische Klinik

Berlin vol. 34 October 7, 1938

- Clinical Picture of Hormonal Insufficiency in Women. K. Sommer.—p. 1315.
Sterility Due to Spasm of Tubes: Causation and Treatment. W. Breipohl.—p. 1316.
Hallux Valgus Complex. C. Mah.—p. 1317.
*Air and Light Treatment of Surgical Tuberculosis. H. Alexander.—p. 1321.
Disorders following Injections of Drugs containing Quinine. K. Schwartz.—p. 1324.
Intravenous Injections of "Trasentin." J. Jansen.—p. 1326.
Treatment of Haemorrhagic Diatheses with Vitamin C. G. Walther.—p. 1327;
Concluding Remarks by H. Winckelmann.—p. 1329.
Hysteria and Compensation Neurosis in Social Insurance. F. Pfeffer.—p. 1330.
Treatment of Septicaemia: General Review. M. Haedicke.—p. 1333.

Air and Light Treatment of Surgical Tuberculosis.—Surgical tuberculosis is considered as a general and not a local affection. The dietetic and the climatic therapy may be advantageously combined with orthopaedic treatment; 80 per cent. of permanent cures are reported. The duration of the treatment varied between fifteen and twenty-seven months, and was longer in the presence of infected fistulae.

- Thyroid and Circulatory System. H. Löhr.—p. 1443.
*Injection Treatment of Deformed Joints. W. König.—p. 1446.
Results of Protracted X-ray Therapy of Laryngeal and Pharyngeal Tumours. G. Kriessmann.—p. 1450.
Asthma and Workmen's Compensation Cases. A. Welzel.—p. 1453.
Trauma in Production of Cardiac Valvular Deficiency. H. Lucke.—p. 1456.
Excretion of Prolan in Male. J. Ritzke.—p. 1457.
Treatment of Blepharitis. V. Schreiner.—p. 1458.

Injection Treatment of Deformed Joints.—Diseases producing deformity in joints are, according to König, unsatisfactorily treated in practice. A correct diagnosis followed by removal of all foci of infection is essential. The joints themselves require correction of the deformity by physiotherapy; contractures should be overcome by the injection of novocain into the soft parts, and changes in the joints themselves should be treated by injections of metallic agents.

Decarboxylation of Aspartic and Glutamic Acids. A. I. Virtanen, P. Rintala, and T. Laine.—p. 674.
Dose and Response in Vitamin E Treatment. A. L. Bacharach.—p. 675.

Responsivity to Oestrone Injection.—Dr. J. Duszynska describes a seasonal rhythm in the response of castrated

albino mice to injections of oestrone, similar to that reported in the case of the action of androgen on capons. The response is greater in spring than in autumn. This variation affects the conclusions arrived at from biological assays by the vaginal smear methods, unless carried out in comparison with standard preparations.

*Uretero-pyelography in Infants. R. Bouchard.—p. 1472.
*Angiocardiography in Children. A. Castellanos, R. Pereira, and A. Garcia.—p. 1474.

Electro-encephalograms in Epilepsy.—As a result of the examination of thirty-three cases of major and minor epilepsy, the authors consider that electro-encephalography may prove to be useful in the prognosis and treatment of epilepsy; characteristic waves are obtained during the attacks and all severe or intractable cases also show abnormal waves in the intermediate periods.

Uretero-pyelography in Infants.—The author is of the opinion that this procedure is quite safe and fairly easy for an expert. He advocates its use in cases of pyuria and abdominal tumour in infants or young children as it yields much more definite and reliable information than does urography.

Angiocardiography in Children.—The authors, after a short historical survey, describe their own methods and some results obtained in both normal and pathological cases.

Paris vol. 46 October 5, 1938

Kidney and Arterial Hypertension. L. Langeron and R. Deboeck—p. 1481
 *Gold Treatment of Bronchial Asthma. Autodesensitization of Body by Means of Hyposulphites. I. Vignani, V. Malaf, and S. Rabinowitch—p. 1482

Kidneys and Blood Pressure.—The authors discuss the relation between the kidneys and hypertension from the pathological, clinical, experimental, physio-pathological, and therapeutic points of view, and conclude that recent knowledge confirms the classical view of the importance of the kidneys in hypertension.

Gold Treatment of Bronchial Asthma.—The authors have treated thirty-five cases since 1933 with twenty-seven "complete and lasting successes." The therapeutic effects are due to a combination of various factors: the anti-anaphylactic action of sulphur, the influence of various cations, the affinity of gold for pulmonary tissue. The presence of the allergen responsible for the asthma is also essential.

Influenza and Heart Disease.—After an influenzal attack the bundle of His may be affected with resultant partial heart-block, which may last for a long time if not treated. Influenza does not affect the valves of the heart, and has little action on the healthy myocardium, but it may produce a serious increase in a pre-existing myocarditis. Influenza is probably of more importance in causing or increasing heart disease than has hitherto been realized.

Undesirable Tuberculin Reactions (Eng.). H. Behrendt.—p. 129.

Urinary Antiseptics.—Mandelic acid acts only in acid urine; sulphanilamide acts best in an alkaline urine. The former is the drug of choice in infections due to *Streptococcus faecalis*. The latter, because of the ease of administration, is the best drug in the average case. It is the drug of choice in acute infections, in *proteus* infections, and in patients with reduced renal function. Helmholz points out that organic acids and sulphanilamide supplement each other according to the types of organisms producing the urinary infection.

Intra-ocular Homotransplantation of Prepubertal Testes in Rat. C. D. Turner.—p. 101.

Thyroid Deficiency in Sheep.—This study is based upon the skulls and/or skeletons of five pairs of twin sheep, one of each pair being thyroidectomized in early life. There were also five other sheep of which there were no normal twins. These were compared with normal skeletons in the Hamann and Hunterian Museums. The effect of hypothyroidism is not evident until the animal is 3 months old, when there occurs a diminution in the gain of weight. There is inhibition in the velocity of growth without prolongation of the growth period. Obvious pathological changes are not evident in the diaphyso-epithelial plane until the animal is 2 years old. The disturbance in the growth of the skull affects chiefly the region of the premaxilla and maxilla. Eruption of the permanent teeth is delayed, and the normal sequence of eruption is disturbed.

Convulsive (Pentamethylenetetraval) Shock Therapy in Depressive Psychoses. A. E. Bennett.—p. 420.

Haematopoietic Principle in Diseased Human Liver.—Extracts were prepared post mortem from five human livers of cases with chronic liver disease. They were shown to contain the haematopoietic principle by injection into a suitably controlled group of patients suffering from pernicious anaemia in relapse. Although three extracts were prepared from the livers of patients with cirrhosis who had suffered from macrocytic anaemia, they produced characteristic reticulocytosis, increase in haemoglobin and red cell count, and marked clinical improvement. This suggests that the macrocytic anaemia associated with liver disease is not caused by a failure of the liver to store the specific anti-anaemic substances.

Rapid Desensitization in Insulin Hypersensitivity.—The patient was proved to be allergic even to pure crystalline insulin, which caused urticaria and a local wheal upon intracutaneous injection. By means of small, slowly increasing doses at short intervals desensitization was accomplished within fifteen hours and the reactions to intracutaneous tests became completely negative after twenty-four hours.

Paredrine.—Paredrine, a sympathomimetic, used three minutes after one drop of 1 per cent. atropine produced maximal cycloplegia in children up to the age of 16 in sixty minutes; recovery occurred in three days. In older patients homatropine instead of atropine was used. There was no irritation or rise of intra-ocular tension.

Lymph Node Metastasis of Sarcoma S. Watten and R. W. Meyer—p. 605.
Primary Liposarcoma of Bone J. Duffy and I. W. Stewart—p. 621.

Lymph Node Metastasis of Sarcoma.—The proportion of cases in which sarcoma metastasizes in lymph nodes is very variously stated, but is usually believed to be small. Of 237 cases observed by the authors, a series from which lymphosarcoma and certain other growths were excluded, seventeen (7 per cent.) were proved to have metastases in lymph nodes. The dissection of neighbouring lymph nodes during operation for the radical removal of a sarcoma is said to improve the prognosis.

Experimental Evidence supporting Conception of "Adaptation Energy" H. Selye—p. 755.
Respiratory Effects from Application of Cocaine, Naloxone, and Lobeline to Floor of Fourth Ventricle H. C. Nicholson and S. Sobin—p. 766.

Massive Doses of Insulin.—In the treatment of schizophrenia by insulin shock therapy there is a moderate increase in the concentration of the serum proteins and a marked decrease in the concentration of potassium; the latter is ascribed to hyperactivity of the adrenal glands provoked by the hypoglycaemia.

Renal Clearances of Organic Iodine Compounds.—Organic iodine compounds are excreted in part by the renal tubules and the clearances are depressed as the plasma concentration is elevated. All these substances depress the phenol-red clearance. They are apparently excreted by the same common cellular mechanism and thus enter into quantitative competition for that mechanism.

Human Dietary Night Blindness.—The subject was markedly hemeralopic due to vitamin A deficiency. Following temporary cure with a single dose of vitamin A, hemeralopia reappeared with greatly increased rapidity, presumably due to depletion of vitamin A reserves during the initial deficiency. The development of hemeralopia was repeatedly checked temporarily by the oral administration of vitamin A or carotene. The behaviour of the cones parallels that of the rods. Vitamin A appears to be the precursor of cone visual pigments as well as of the rhodopsin of the rods. The night blindness was cured by giving milk, butter, fresh fruits, vegetables, and vitamin A, and the subject then possessed perfectly normal visual adaptation and was otherwise in good health.

Ascorbic Acid and Body Weight.—Guinea-pigs fed for twenty-one days on a scorbutic diet plus ascorbic acid were significantly heavier than others of the same initial weight receiving only the basal diet, even when the food intake of the two groups of animals was the same. Since the difference was not due to lower food intake associated with loss of appetite, it might be accounted for by alterations in metabolism, water balance, and food absorption caused by lack of ascorbic acid.

Effect of Splenectomy and Blockade on Protective Titer of Antisera against *Trypanosoma equiperdum*. L. R. Kuhn.—p. 217.

Bacterial Colony Variation.—A strain of *Bact. paratyphosum* B gave rise to dwarf-colonized variants resembling the G type of *Bact. dysenteriae* Shiga described by Hadley and others. These colonies were composed of coecal elements, which passed Berkefeld filters, were more thermoresistant than the normal form, and were entirely insusceptible to bacteriophage. Reversion to the normal form was not

observed. The description of these findings is followed by a long review of previous observations on bacterial variation of this kind and a discussion of its possible implications.

Tuberculin Patch Test.—This test was found to be as reliable as the Mantoux test and painless. For this reason it is to be preferred for children; no instruments are needed. There are no severe local or constitutional reactions, nor is there any chance of infection.

Journal de Physiologie et de Pathologie Générale

Paris vol. 36 September, 1938

- Effect of Local Anaesthetics on Chronaxie and Resistance of Isolated Nerves. J. Renier and A. Quevauxville—p. 629
Determination of Euglobulin and Pseudoglobulin in Normal and Pathological Human Serum. C. Hecht—p. 652
"Residual" "Chromic Index" in Plasma of Diabetic. M. R. Dandurand—p. 669
Effect of Removal of Mammary Glands on Blood Sugar and on Liver and Muscle Glycogen in Lactating Guinea-pig. M. Cahare—p. 679
Effect of Adrenaline in Large and Small Doses on Anaesthetized Animal (Amphomimetism). Dan elopoli and J. Marcon—p. 681
Passage Into Nervous System of Urea Injected into Blood. M. Riser, P. Valadier, and J. Guiraud—p. 694

Residual "Chromic Index" in Diabetes.—In addition to glucose, normal deproteinized plasma contains substances which are destroyed by potassium dichromate in acid solution. The "residual" index, which is arrived at after allowing for the destruction due to glucose oxidation, is increased in simple diabetes and more extensively in consumptive diabetes, the increase being proportional to the severity of the symptoms. Insulin therapy abolishes this increase, and it is suggested that accumulation of these unknown substances is due to the failure of normal steps in carbohydrate metabolism.

Passage of Urea into Nervous System.—A rapid rise in blood, brain, and muscle urea occurred in dogs under chloralose anaesthesia receiving 2 to 3 grammes per kilogramme of body weight of urea intravenously. The maximum rise was reached in fifteen minutes, except in the cerebrospinal fluid, in which this only occurred in two to two and a half hours, though after this the urea concentration in the cerebrospinal fluid paralleled the blood-urea concentration; the same lag occurred if the ureters were tied. It is not considered to represent any special property of the meningeal membranes but to be due to the smallness of the available interchange surfaces.

Journal of Urology

Better Medical Writing: Some Typical Errors and How to Avoid Them. R. M. Hewitt—p. 454
Gangrene of Glans Penis and Urethra in Diabetic. T. M. Townsend and W. M. H. Ez—p. 464

Multiple Primary Cancers.—A detailed description is given of five personal cases of multiple malignant neoplasms with special reference to those of urogenital origin. In three instances there were found independent growths arising in two different organs of the genito-urinary system; in one instance there was a growth of the prostate together with an epithelioma of the ear; and the fifth patient manifested three concomitant carcinomata originating respectively in the bladder, the prostate, and the colon. These comparatively rare cases are discussed, and also certain clinical fallacies in their diagnosis. A bibliography is appended.

Monatsschrift für Kinderheilkunde

Berlin Bd. 76 October 22, 1938 Heft 1 and 2

- Human Immunity to Tuberculosis. H. Vogt—p. 1
Appendicitis in Childhood. F. Wenzler and J. Müller—p. 11

Aetiology of Mononucleosis. W. Tobler—p. 62
Nucleosis Erythraemia. A. Sakamoto and K. Yukune—p. 72
Development of Premature Infants. W. Schöberlein—p. 80
Scarlet Fever. F. S. Bornmann—p. 107
Dietetic Disturbances in Infants. H. Vogt—p. 114

Premature Infants.—Schöberlein examined ninety-six children who had been born prematurely. They were between the ages of 6 and 18. At the end of the second year of life 73 per cent. were able to walk and 48 per cent. were able to talk; 42 per cent. were described as nervous; 63 per cent. as being less able to concentrate than normal children; 55 per cent. as more easily fatigued. Of the boys 25 per cent. had undeveloped testes, 16 per cent. of the children were above normal intelligence, 25 per cent. below it. The author believes that the number of premature infants must be reduced by better ante-natal care and improvement in social conditions in order to reduce the high mortality (in his series 47 per cent.).

Coarctation of Aorta: Three Cases with Necropsy Findings in One. T. B. Weinberg and C. Gartenlaub—p. 445
Effect of Radiation Applied Directly to Brain and Spinal Cord. I. Experimental Investigations on *Macaca rhesus* Monkeys. L. M. Davidoff, C. G. Dyke, C. A. J. Berg, and I. T. Tarlov—p. 451

- Characteristics of X Rays. J. L. Weatherwax.—p. 464.
Concerning Diagnosis of Lesions in Lower Spinal Canal. J. C. Bell and R. G. Spurling.—p. 473.
Radium Protection: Advisory Committee on X-ray and Radium Protection.—p. 481.
Bulletin of Inter-society Committee for Radiology: What is the Issue? M. C. Cialli.—p. 491.

Sensitization.—The direct electric current can produce sensitization to x-radiation in normal rabbit tissue, producing an intense local reaction which gradually fades beyond the limit of the electrode. The use of this method to intensify the effect of external radiation in the treatment of malignant disease has at least a logical as well as an experimental background.

Normal Coccyx.—Angulations at the sacro-coccygeal and first coccygeal articulations are to be found in the normal spine, but cases presenting an appreciable variation constitute only a small proportion of the total number. The variation may occur in either the transverse or the sagittal plane and, more rarely, in both.

Rivista di Neurologia

Naples vol. 11 August, 1938

- Neurological Syndrome of von Recklinghausen's Neurofibromatosis. F. Vizioli and S. Tolone.—p. 281.
Multiple Cerebral Glioblastoma of Pons and of Corpus Callosum without Psychic Symptom. D. Alessi.—p. 321.
*Spasmodic Scoliosis in Differential Diagnosis between Lumbar Pain Symptomatic of Compression of Cauda Equina and Protracted Idiopathic Lumbar Pain. C. Masci.—p. 340.
*Motor Paralysis in Herpes Zoster. F. Rocchi.—p. 367.

Spasmodic Scoliosis.—As a result of the study of a large number of cases the author establishes the rarity of scoliosis in compression of the cauda equina and its common occurrence in protracted idiopathic lumbar pain. This sign is therefore useful in differential diagnosis. The idiopathic forms should be regarded as manifestations of lumbar arthritis with an accompanying neuralgia.

Motor Paralysis in Herpes Zoster.—Two cases of motor paralysis in herpes zoster are described, one of the abdominal wall—not easily diagnosed—and the other of the face. The various aspects of this condition are discussed, and the author points out that when the virus of herpes zoster affects cells of the anterior horn it behaves as do other neurotropic viruses, picking out certain groups of cells.

Rivista di Patologia Nervosa e Mentale

Siena vol. 52 July-August, 1938

- Torsion Spasm with Atletosis. P. E. Maspey and A. Romero.—p. 1.
On Problem of Hallucinations. A. Romero.—p. 17.
Agreement of Seroreactions of Takata and Weltmann with Pathogenic Factors of Schizophrenia. A. Zalla.—p. 66.
Multiple Tubercles in Brain. A. Romero.—p. 81.
*Pathogenic Interpretation of Occipito-cervical Pain and of Cervical Rigidity in Some Meningo-encephalitic and Sinus Affections. C. Piero.—p. 100.
Use of Centrifuge in Lange Reaction and Mastix Reaction. R. Bozzi.—p. 128.
Appearance of Interfascicular Oligodendroglia and their Homology with Cells of Schwann. F. Loreti.—p. 135.
*Interruption of Synergy of Ocular Movement during Insulin Coma. G. Curti.—p. 171.

Occipito-cervical Pain.—The author has superficially anaesthetized the nasal mucosa in some cases of typical and atypical trigeminal neuralgia and in cases of head pain not of nasal origin. In eight cases in which a nasal origin of the pain was not suspected, and in which no lesion could be found in the nose, relief of the pain was immediate, as it was in four cases of pain definitely due to other causes. The author thinks this is due to a general reduction of sensory impressions reaching the brain and that intracranial painful stimuli will not reach the threshold of consciousness unless reinforced by the sensory impressions from the nose.

Insulin Coma.—The author has observed an interruption of the synergy of ocular movement during insulin coma in cases of dementia praecox treated with insulin. He regards it as a release phenomenon induced by the abolition of higher (conscious) cortical control.

Zeitschrift für Hygiene und Infektionskrankheiten

Berlin vol. 121 September 5, 1938

- Epidemiology and Epidemiography of Cholera in Russia. R. Olzcha and H. Zeiss.—p. 1.
*Researches on Possibility of Transmission of *Trichomonas vaginalis* by Bath-water. P. Weiter.—p. 27.
*Preparation and Assay of Rabbit Pneumococcus Serum. F. Kauffmann, M. Bjørneboe, and B. Vammen.—p. 36.
Specific Protein in Rabbit Pneumococcus Serum. M. Bjørneboe.—p. 56.
Effect of Bactericides on Human and Bovine Tubercle Bacilli: III, Experiments with Certain Rapid-acting Agents in Alcohol and Phenol Groups. E. Haifer.—p. 67.
*So-called "Thrust-pipe" in Water Supplies. F. Weyrauch.—p. 75.

***Trichomonas vaginalis* and Bath Water.**—The water of a large number of open-air and indoor swimming-baths was examined for *Trichomonas vaginalis* with invariably negative results. This protozoon is sensitive to cold, sunlight, and chlorine, and is therefore probably killed in the water of swimming-baths. On the other hand, the domestic bath, especially when for any reason several persons use the same same water, is a possible vehicle of transmission.

Rabbit Serum in Pneumonia.—This paper records the technique used for immunizing rabbits in the preparation of anti-pneumococcal therapeutic serum. Serum was prepared for all thirty-two types, and therapeutic trials in Denmark are briefly described as giving admirable results.

"Thrust-pipe" in Water Supplies.—In outlying districts it is the custom to supplement the public water supply by means of a pipe thrust into the bed of a near-by stream. Such pipes may be hidden or forgotten. The danger of consequent water-borne epidemics is commented upon, and a simple device for the chlorination and filtering of such accessory water supply is described and illustrated.

Occurrence of Nitrous Gases in Use of Schamotte Gas Burner for Heating Purposes. F. Sander.—p. 142.
Hygienic Investigation of Wells in Relation to Security of Water Supply of Towns. B. Schmidt.—p. 148.
*On Germicidal Properties of Garlic (*Allium sativum*). O. E. Böcker.—p. 166.

Staphylococci and Encapsulated Bacteria.—On agar media the presence of *Staph. aureus* or of *Staph. albus* not only restrains the growth of, but acts as a bactericide to, *B. rhinoscleromatis*, *B. ozaenae*, and Friedländer's bacillus. Filtered bouillon cultures exhibit the same antagonistic action. The author concludes that this is due to a thermostable filterable secretion or excretion of the staphylococci incidental to their growth.

Earth Spores in Steam Sterilization.—Native spores found in earth are much more resistant to steam than cultured spores. This high resistance cannot be increased or even maintained by culturing, and so attempts to breed a specially resistant race of spores failed. It is assumed that this property of native spores is due to a chemico-physical influence of the earth itself, is mechanical in nature, and has nothing to do with nutrition. For testing, the impregnation of previously sterilized earth with a known quantity of cultured spores is advised.

Tissue Lipoids and Bacterial Intoxication.—Guinea-pigs so fed as to induce a storage of tissue lipoids did not differ in any way from control animals in regard to diphtheria intoxication.

Garlic.—Garlic exhibits a highly volatile potent germicide, which is active even at a distance (20 cm.). Of the three forms used—infusion, juice, pieces—the potency was in the order given. This effect is not due to "radiation" but to a penetrating exhalation of the nature of a vapour. Organisms planted on culture media exposed to this vapour will not grow.

*A New B.M.A. Specialist
Publication*

BRITISH HEART JOURNAL

The first issue of this new quarterly Journal, jointly edited by Dr. Maurice Campbell and Dr. Evan Bedford, assisted by an Editorial Board appointed by the Cardiac Society, will be published in January, 1939. The new periodical will include matter dealing with everyday diagnosis and treatment of patients and will, therefore, be of value to the general practitioner as well as to the cardiologist to whom it will have an obvious appeal.

An announcement of the contents of the forthcoming number will appear in due course.

HEALTH PROBLEM

"Sunshine and blue skies; farms and homesteads nestling among mountains and hills; blossoms of peach and plum filling the valleys with colour; the perfume of orange groves; the profusion of wild flowers; the camp fire and the thrill of wild game in the Low Veld; the picturesque kraals and laughter-loving natives; the quest of open roads trailing to far horizons; the sparkling air of the High Veld; sea and sun bathing on golden beaches; the bright warm days and cool starlit nights—these memories and the joyous feeling of health and fitness after my last holiday in South Africa will lure me back there before long."

These are a recent visitor's impressions of a South African holiday.

Those concerned with problems of health might well consider the benefits to be derived from exchanging the rigours of a European Winter for "Sunshine and blue skies." It is now only a fortnight's voyage to

SOUTH AFRICA

Illustrated brochures, including one entitled "Medicinal Springs of South Africa," are obtainable from the Travel Bureau, South Africa House, London, W.C.2.

Improvements in OPHTHALMOSCOPES

The Gowlland improved May Ophthalmoscope has illuminated and magnifying numbers. The figures are brilliantly illuminated by the Ophthalmoscope lamp and magnified to nearly twice the size of those in the older type of instrument. They are positioned well away from the sight-hole and cannot interfere with the observation.

The patch of light projected is bright and absolutely even, while the reflecting prism is adjusted so that there are no shadows and that the corneal reflex is minimised.

Gowlland
electric diagnostic instruments

Made in England.

OBTAINABLE FROM ALL SURGICAL
INSTRUMENT DEALERS.

AURISCOPES

The Friston Auriscope has black moulded bakelite specula, which are practically unbreakable, never feel cold for the patient and, being black inside, eliminate glare into the user's eye. The shape allows ample internal space for manipulation.

The gift for the motorist

What better Christmas gift than a set of sparking plugs? Automatically the choice should be Lodge, the best plug in the world, fitted by the makers of the world's best cars. No matter what make or year of car, a new set of Lodge will renew engine vitality.

LODGE

THE BEST PLUG IN THE WORLD

USED BY THE FASTEST MOTORIST ON EARTH!
357.5 m.p.h. was the amazing new World's Land
Speed Record set up by Capt. G. E. T. Eyston,
using 'Lodge' Plugs in his Rolls-Royce engines.

“Why should I prescribe the **CURTIS** Abdominal Support?”

RTM

Because the Curtis Abdominal Support No. 1 is the most efficient obtainable for all forms of Abdominal Ptosis.

It is light in weight, and gives maximum support by direct anterior-posterior pressure. There is no undue constriction of the lower abdomen with the Curtis and it allows complete freedom of the hips.

That is why leading London Hospitals and the Medical Profession recommend this safe and scientific support!

Modern Iron Therapy

Iron Jelloids are an elegant and reliable means of administering the protoearbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidised indefinitely, and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of aehlorhydrie anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D., M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the preferred immersion bath, Vichy Douches, Scotch Douches, Electrical bath, Pneumatics treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat fruit and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 350 acres, Llanfairfechan, amidst the forest scenery in North Wales. On the South West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, tennis courts, lawns and hard courts, croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, etc. For terms and further particulars apply to the Medical Superintendent (Telephone No. 2196 and 2197 Northampton), who can be seen in London by appointment.

CRICHTON ROYAL, DUMFRIES for NERVOUS AND MENTAL DISORDERS

Cases of alcoholism and drug addiction are admitted.

This Hospital has every facility for complete investigation and treatment of the above conditions.

The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy. There is a fully equipped Gymnasium and indoor Swimming Bath under qualified instructors. Facilities are provided for all indoor and outdoor recreation, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens, and a Cinema.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country, and include an extensive farm (T.T. herd), gardens and orchards.

Private rooms, suites or villas are available, and special nurses can be provided.

As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week; Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Supt. P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law Tel. Dumfries 1119.

EDINBURGH POSTAL COURSES.

Full details of above and Oral Classes.—H. C. ORRIN, F.R.C.S., Surgeon's Hall, Edinburgh.

CITY OF STOKE-ON-TRENT EDUCATION COMMITTEE.

SENIOR SCHOOL DENTAL OFFICER.

The Stoke-on-Trent Education Committee invite applications from fully qualified and registered male dental surgeons for the post of Senior School Dental Officer.

Salary will be at the rate of £600 per annum, rising by annual increments of £25 to £700 per annum.

The successful candidate will be required to devote the whole of his time to the duties of the office and work under the direction of the Senior Medical Officer. The duties will consist of supervision of the Authority's Dental Officers, school dental inspection and treatment, the dental treatment of Maternity and Child Welfare Centre patients, and patients of the County Borough Institutions, as required. He must be prepared to undertake clinical work in addition to his supervisory duties.

Previous experience in school dental work for at least three years is essential. Canvassing will be considered a disqualification.

Forms of application may be obtained from the undersigned on receipt of a stamped, addressed, business envelope, and completed forms should be submitted not later than January 5th, 1939.

The appointment will date from May 1st, 1939, and will be subject to the Local Government Superannuation Act, 1937.

J. F. CARR.

Director of Education.

Education Office

Town Hall,

Stoke-on-Trent.

November 30th, 1938.

BOARD OF CONTROL. ENGLAND AND WALES.

The Board of Control (Lunacy and Mental Deficiency) invite applications from registered medical practitioners (men and women) for a vacant appointment as COMMISSIONER on the BOARD'S STAFF.

Candidates should be experienced in the care and treatment of persons suffering from mental disorder or mental defect.

The salary commences at £850 per annum, and rises by eleven annual increments of £30 to £1,180 and then to £1,200 per annum. In the case of a candidate with special experience of the administration of mental institutions the commencing salary may be advanced to a point, not exceeding £75, above the minimum of the scale.

The appointment will be subject to the usual Civil Service conditions as to pension, holidays, etc., and also, in the case of women, marriage. Subject to certain conditions, previous established service in a Mental Hospital or Mental Deficiency Institution can be aggregated with Civil Service for superannuation purposes.

Commissioners are required to devote their whole time to the Public Service.

Canvassing through Members of Parliament or in other ways will render a candidate liable to disqualification.

Forms of application, with further particulars of the appointment, may be obtained from the Secretary, Board of Control, Hobart House, Grosvenor Place, London, S.W.1.

No application can be considered unless received on the prescribed form not later than January 7th, 1939.

CITY OF PLYMOUTH. CITY GENERAL HOSPITAL (570 Beds).

Applications are invited from duly qualified and registered medical practitioners for the post of JUNIOR ASSISTANT MEDICAL OFFICER. Salary at the rate of £250 per annum, with full residential. All fees received by the Officer must be refunded to the Council.

The appointment will be for the period of six months in the first instance, and renewable for a further period of six months, and will be terminable by one month's notice on either side.

The duties of the post will be largely on the surgical side of the Hospital.

Further details may be obtained from the Medical Superintendent.

Forms of application may be obtained from the undersigned, and should be forwarded, together with copies of not more than three recent testimonials, not later than December 29th.

Town Hall,

Stonehouse,

Plymouth.

T. PEIRSON,

Medical Officer of Health.

GUY'S HOSPITAL—DENTAL SCHOOL.

Applications are invited for the WHOLE-TIME POST OF DENTAL RESEARCH FELLOW. The appointment to begin as soon after January 1st, 1939, as possible. Preference will be given to a biochemist who is prepared to undertake work on dental diseases. The appointment will be for two years in the first instance with the possibility of reappointment. The stipend will be at the rate of £400 per annum.

Applications, accompanied by the names of three persons to whom reference may be made, should be submitted not later than December 31st, 1938, to the Dean, Guy's Hospital Medical School, S.E.1, from whom further particulars regarding the appointment may be obtained.

NORMAN GAMBLE RESEARCH FUND OF THE ROYAL SOCIETY OF MEDICINE.

Applications from individuals (British subjects) for GRANTS IN AID OF RESEARCH IN OTOTOLOGY should be made to the Secretary of the Royal Society of Medicine, 1, Wimpole Street, London, W.1, not later than February 28th, 1939. Applicants should give full particulars of the work proposed.

EXPERIENCED COACHING IN PHYSIOLOGY, Pathology, and Medicine by M.D. Lond. (Hons.), M.R.C.P.Lond., B.Sc. Physiology Lond. All exams. Classes held.—Address, No. 7902, B.M.A. House, Tavistock Square, W.C.1.

UNIVERSITY COLLEGE HOSPITAL. BILTON POLLARD FELLOWSHIP.

Applications are invited for the above FELLOWSHIP of an annual value of £650, commencing February 1st, 1939, the tenure of which is limited to the men students of University College Hospital who have held a resident appointment or its equivalent at the Hospital.

Candidates must hold the qualification of M.R.C.P. (London) or F.R.C.S. (England), and must declare their intention of engaging in the practice of medicine or surgery.

Forms of application can be obtained from the Secretary of University College Hospital, Gower Street, W.C.1, and must be returned not later than Monday, January 2nd, 1939.

UNIVERSITY COLLEGE HOSPITAL.

Applications are invited for the whole-time post of ASSISTANT to the Department of Radiotherapy. The salary will be at the rate of £500 per annum.

Applications, accompanied by such evidence of fitness for the post as the candidates may desire to furnish, should reach the Secretary, University College Hospital, Gower Street, W.C.1, not later than Monday, January 2nd, 1939.

CITY OF LIVERPOOL.

SENIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the above appointment at the Alder Hey Children's Hospital, West Derby, Liverpool (940 beds), for a period of twelve months in the first instance.

Candidates must be single, fully qualified and registered, and should, preferably, have had considerable experience in diseases of children and possess one of the higher qualifications in medicine.

Salary at the rate of £350 per annum, rising by annual increments of £25 to £450 per annum, together with the usual residential allowances. All fees received in connexion with the appointment to be handed over to the City Council.

The position offers exceptional opportunity for anyone wishing to specialize in diseases of children.

The person appointed will be required to work under the direction of the Medical Superintendent.

The appointment will be made in accordance with the Standing Orders of the City Council and will be determinable by three months' notice on either side. Canvassing, either directly or indirectly, will be deemed a disqualification.

Applications upon forms obtainable from the Medical Officer of Health, Hospitals Department, Liverpool, 2, to be endorsed "Senior R.A.M.O.", and returned to the undersigned so as to be received not later than Friday, December 30th, 1938.

Municipal Buildings,

Liverpool, 2.

December, 1938.

W. H. BAINES, Town Clerk.

SURREY COUNTY COUNCIL.

PUBLIC HEALTH DEPARTMENT.

FARNHAM COUNTY HOSPITAL (197 Beds)

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of Assistant Medical Officer at the Farnham County Hospital, Hale Road, Farnham.

Candidates must have held resident hospital appointments and should preferably possess a higher qualification.

The tenure of the appointment is limited to a period of five years, but the appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. The cash salary is at the rate of £350 per annum, rising by annual increments of £25 to a maximum of £450 per annum, together with full residential emoluments valued at £125 per annum.

Applications, stating age, qualifications and experience, and enclosing copies of not more than three recent testimonials, should be addressed to the County Medical Officer, County Hall, Kingston-on-Thames, so as to be received not later than December 21st, 1938.

County Hall, DUDLEY AUKLAND,

Kingston-on-Thames. Clerk of the Council.

December 9th, 1938.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry at the end of March, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list. Marriage Allowance is paid under the same conditions as for other Naval Officers.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1. and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1939.

Appointments for Medical Officers in the ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force. Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry.

The period of service is 3 years—extendable to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study. Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission up to twelve months is allowed for appointments held at approved hospitals.

*Fuller information can be obtained from The Director
of Medical Services, Air Ministry, Kingsway, London.*

BOROUGH OF LEYTON.

DEPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER.

Applications are invited from registered medical practitioners possessing a registered Diploma in Public Health or State Medicine for the appointment of Deputy Medical Officer of Health and Deputy School Medical Officer.

Age not to exceed 45 years.

The salary attaching to the post will be £660 per annum, rising by four annual increments of £20 and one of £10 to a maximum of £750 per annum.

Preference will be given to candidates possessing previous experience in school medical inspection, maternal and child welfare, and in the diagnosis and treatment of infectious diseases.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, or, in the event of the person appointed taking up his duties after March 31st, 1939, to the provisions of the Local Government Superannuation Act, 1937, and to the conditions set out on the form of application.

Applications must be made on the prescribed forms, which can be obtained by sending stamped addressed foolscap envelope to the undersigned.

Applications, endorsed "Deputy Medical Officer of Health," must reach the undersigned as soon as possible and not later than the first post on January 2nd, 1939. Canvassing, directly or indirectly, will be a disqualification.

Town Hall, JNO. ATKINSON,
Leyton, E. 10, Town Clerk.
December 9th, 1938.

CITY OF LEEDS.

PUBLIC HEALTH DEPARTMENT.

ST. MARY'S INFIRMARY, ARMLEY,
LEEDS, 12.

RESIDENT MEDICAL OFFICER.

A Resident Medical Officer is required for St. Mary's Infirmary, Leeds (250 beds). The hospital is a general hospital for chronic and semi-chronic cases, with a section of 25 beds devoted to Maternity.

The appointment is for twelve months, and the salary is £250 per annum inclusive, together with full residential emoluments. Any fees received must be paid into the City funds.

Candidates must have had experience in midwifery subsequent to qualifying. The duties of the officer include lecturing to the Nursing Staff and instruction of Pupil Midwives.

Applications, stating age, qualifications, etc., together with copies of three recent testimonials, to be forwarded to the undersigned not later than 10 a.m. on Saturday, December 24th, 1938.

Canvassing in any form, either directly or indirectly, will be a disqualification.

J. JOHNSTONE JERVIS,
Medical Officer of Health.

Public Health Department,
12, Market Buildings,
Vicar Lane, Leeds, 1

BOROUGH OF HOVE.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered medical practitioners under the age of 40, for the above whole-time appointment. The duties will be of a general nature, but special experience is necessary in Maternity and Child Welfare and Infectious Diseases, and applicants should possess the Diploma of Public Health.

The salary will be £500 per annum, rising by annual increments of £25 to £700 per annum, together with a car allowance of £50 per annum. The successful candidate will be required to pass a medical examination and to contribute to the Superannuation Fund.

Applications, on the prescribed form, to be obtained from the undersigned, together with copies of three recent testimonials, must be received not later than Friday, December 30th, 1938.

Town Hall, W. JERMYN HARRISON,
Hove, Town Clerk.
November, 1938

CITY OF BIRMINGHAM.

Dudley Road Hospital. (926 Beds.)

Applications are invited from fully qualified Medical Practitioners for whole-time appointment as JUNIOR MEDICAL OFFICER (male) at the Dudley Road Hospital, Birmingham. The appointment will be for a period of six months, but may be extended for a further period of not exceeding six months. Salary at the rate of £200 per annum, and full residential emoluments.

Further particulars may be obtained from the Medical Superintendent at Dudley Road Hospital, to whom applications, stating age, experience, and qualifications with copies of recent testimonials, should be forwarded not later than Thursday, December 24th, 1938.

COUNTY BOROUGH OF DERBY.

ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the post of Assistant Medical Officer in the Public Health and School Medical Department. Salary £500 per annum, rising by annual increments of £25 to £700 per annum.

Applicants must be duly qualified registered Medical Practitioners, and should possess the Diploma of Public Health.

The duties of the post are the medical inspection of school children, the supervision of treatment of minor ailments, the carrying out of work under the maternity and child welfare scheme, and such other duties as may be required by the Council.

The officer appointed will be required to devote his whole time to the duties of the post, to act under the supervision and control of the Medical Officer of Health, and to reside within the Borough.

The successful candidate will be required to contribute to the Council's Superannuation Fund, and for this purpose must pass the necessary medical examination. Age of applicant must not exceed 40 years.

The appointment will be held during the pleasure of the Council, and is terminable by two months' notice on either side.

Applications, stating age, qualifications, and previous experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than Wednesday, December 28th, 1938. Application forms are not provided. Envelopes must be endorsed "Assistant Medical Officer."

Canvassing, directly or indirectly, will be a disqualification.

F. C. SMITHARD,
Secretary to the Education Committee,
Education Offices,
Becket Street, Derby.

COUNTY BOROUGH OF MIDDLESBROUGH.

ST. LUKE'S MENTAL HOSPITAL,
Grove Hill, Middlesbrough.

The Committee of Visitors invite applications for the appointment of ASSISTANT MEDICAL OFFICER and DEPUTY MEDICAL SUPERINTENDENT (male) for the above-mentioned Hospital.

Candidates must be fully qualified and duly registered, and preference will be given to one who has held a resident appointment in a General Hospital.

The age of applicants, unless with previous Mental Hospital service, should not exceed 35 years.

Salary £500 per annum (no emoluments), rising by four annual increments of £25 to a maximum of £600, plus an extra payment of £50 per annum to holders of, or who may later obtain, the D.P.M. Unfurnished house on the estate provided, for which a sum of £50 per annum will be deducted from the salary to cover rent, rates and water.

The appointment is whole time and subject to the provisions of the Asylums Officers' Superannuation Act, 1909. The appointment will be terminable by two months' notice on either side. The successful candidate will be required to undergo a medical examination.

Canvassing will disqualify. Applications, accompanied by copies of three recent testimonials, should be sent to the undersigned not later than January 4th, 1939, endorsed "Assistant Medical Officer and Deputy Medical Superintendent."

PRESTON KITCHEN,
Town Clerk and Clerk to the
Town Clerk's Office, Committee of Visitors,
Middlesbrough,
December 7th, 1938.

COUNTY BOROUGH OF OLDHAM.

MUNICIPAL HOSPITAL.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the post of Resident Assistant Medical Officer. Applicants must not be over 45 years of age.

Salary £200 per annum, with board, residence, and laundry.

Candidates should be unmarried. The appointment will, in the first instance, be for a period of six months. The successful applicant, however, will be eligible for reappointment for a further period of six months.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

The hospital comprises 375 beds, with facilities for gaining experience in medicine, surgery, midwifery, and diseases of children.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Oldham, and should be returned, endorsed "Resident Assistant Medical Officer," as soon as possible, but not later than 9 a.m. on Wednesday, December 28th, 1938.

Town Hall, THOMAS ALKER,
Oldham, Town Clerk.
December 5th, 1938.

NORTHWICH RURAL DISTRICT COUNCIL. NORTHWICH URBAN DISTRICT COUNCIL. WINSFORD URBAN DISTRICT COUNCIL. MIDDLEWICH URBAN DISTRICT COUNCIL.

APPOINTMENT OF WHOLE-TIME MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Practitioners, not exceeding 45 years of age, who are also registered in the Medical Register as holders of a Diploma in Sanitary Science, Public Health, or State Medicine, for the above appointment.

The appointment will be made subject to the approval of the Minister of Health, the provision of Section 110 of the Local Government Act, 1933, and the Sanitary Officers' (Outside London) Regulations, 1935.

The Officer appointed will be required to commence his duties on April 1st, 1939, and devote the whole of his time to the performance of the duties of the office, which will include the Superintendence of the Joint Isolation Hospital.

He will not be permitted to engage in private practice as a Medical Practitioner, will be required to enter into an agreement with each Authority, and to reside within the area.

He will be allowed one month's annual leave. Salary £800 per annum, rising by annual increments of £25 to a maximum of £900, together with a travelling allowance of £150 per annum.

Office accommodation and clerical staff will be provided, and the Officer appointed will be expected to attend Council and Committee Meetings of the Authorities as and when required.

Each Council will designate the position as an Established Post under the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Applications, endorsed "Medical Officer of Health," stating age, particulars of qualifications and local government experience (if any), supported by copies of not more than three recent testimonials, which will not be returned, must be delivered to the undersigned not later than December 24th, 1938.

Canvassing of members of any Authority, directly or indirectly, will be deemed a disqualification.

HAROLD GRANTHAM,
The Council House, Clerk of the Northwich
Northwich, Urban District Council.
December 6th, 1938.

HAMPSHIRE COUNTY COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited for the post of Assistant County Medical Officer. Possession of a Diploma or Degree in Public Health is essential, and previous experience in the various branches of public health, especially tuberculosis, and school medical service work is desirable.

Salary £600 a year, rising, on approved service, by increments to £750 (subject to deductions under the Local Government Superannuation Act, 1937), in addition to travelling expenses.

Applications, with copies of not more than three recent testimonials, upon a form which, with the conditions of appointment, may be obtained from the County Medical Officer, The Castle, Winchester, should be sent to him as soon as possible, and not later than December 30th, 1938. Canvassing is prohibited.

The successful candidate will not be expected to take up his duties before April 1st, 1939.

The Castle, F. V. BARBER,
Winchester, Clerk of the County Council.
December 5th, 1938.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing to undermentioned positions. Candidates must have held resident appointment in a general hospital for at least six months. Married quarters not available.

ASSISTANT MEDICAL OFFICERS (Class D).—Salary £350-£25-£425, with board, lodging and washing.

(a) ST. GILES' HOSPITAL, St. Giles' Road, Camberwell, S.E.5.—Surgical experience desirable.

(b) ST. JAMES' HOSPITAL, Onley Road, Balham, S.W.12.—(Two positions) (1) Surgical duties. (2) Obstetric and gynaecological duties.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division 2, County Hall, Westminster Bridge, S.E.1, returnable by January 2nd.

Canvassing disqualifies.

LONDON COUNTY COUNCIL.

Applications invited from registered medical practitioners of at least one year's standing, resident in the neighbourhood, for appointment as TEMPORARY VISITING MEDICAL OFFICER (part-time) at Earldale House, Children's Reception Home, 1, Safford Road, Wandsworth, S.W.1. Salary £150.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division 2, County Hall, Westminster Bridge, S.E.1, returnable by December 30th. Canvassing disqualifies.

SURREY COUNTY COUNCIL PUBLIC HEALTH DEPARTMENT

EPSOM COUNTY HOSPITAL (130 Beds)

RESIDENT ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the appointment, which will be vacant on February 1st, 1939, of Resident Assistant Medical Officer at the Epsom County Hospital.

Applicants must have held a previous resident hospital appointment and should preferably have had experience in maternity work and minor surgery.

The appointment is for a period of six months, renewable for a further period of six months, and the salary is at the rate of £200 per annum, together with full residential emoluments valued at £125 per annum.

Applications, stating age, qualifications, and experience, and enclosing copies of not more than three recent testimonials, should be addressed to the Medical Superintendent, Epsom County Hospital, Dorking Road, Epsom, so as to be received not later than December 31st, 1938.

DUDLEY AUKLAND,

County Hall, Clerk of the Council
Kington-on-Thames
December 16th, 1938.

ESSEX COUNTY COUNCIL JUNIOR RESIDENT MEDICAL OFFICER.

The County Council of the Administrative County of Essex invite applications for the appointment of a Junior Resident Medical Officer at the Chelmsford County Hospital, Chelmsford.

The appointment is for a period of one year, and the salary will be at the rate of £250 per annum, together with the usual and emoluments valued at £100 per annum. The successful candidate will be required to pass a medical examination, and will be subject to the Council's rules, pay rules and regulations, a copy of which will be forwarded on application.

APPOINTMENTS.—Contd.

THE ELIZABETH GARRETT ANDERSON
HOSPITAL,
Luton Road, N.W.1.

Applications are invited from qualified medical
women for the following posts—
HOUSE PHYSICIAN, FIRST, SECOND, and
THIRD HOUSE SURGEONS, OBSTETRIC
ASSISTANT.

The posts are for six months commencing
February 1st, 1939.

Remuneration at the rate of £50 per annum,
with board, residence, and laundry. Further
particulars of the posts may be obtained from
the undersigned, to whom applications should be sent,
with copies of three testimonials, not later than
Friday, December 30th, 1938.

JEAN R. MURRAY,
Secretary

THE INFANTS' HOSPITAL,
Vincent Square, Westminster.

The Committee of Management invite applications
for the post of **RESIDENT MEDICAL OFFICER**.
Candidates must have held previous resident
Hospital appointments for not less than six months,
and must have had Paediatric experience. The
appointment is for one year from March 1st with
eligibility for reappointment. Salary £300 per
annum, with board, lodging and laundry.

Candidates are expected to call upon, and send
a copy of application and testimonials to, each
member of the Honorary Medical and Surgical
Staff.

Applications, with copies of testimonials, should
be sent not later than January 30th to the under-
signed, from whom copies of the rules may be
obtained.

ARNOLD TUNSTALL.

SOUTH LONDON HOSPITAL FOR WOMEN,

Honorarium £150 per annum.

Applications should be made to the Secretary,
from whom further particulars may be obtained,
and should arrive not later than Saturday, January
14th, 1939.

H. L. MILSON,
Secretary.

CENTRAL LONDON OPHTHALMIC
HOSPITAL,
Judd Street, London, W.C.1.

LOCUM is required for the **SENIOR HOUSE**
SURGEON for two months from February 1st.
Further particulars may be obtained from the
Secretary at the Hospital.

WEST RIDING OF YORKSHIRE MENTAL
HOSPITALS BOARD

APPOINTMENT OF AN ASSISTANT
MEDICAL OFFICER

WADSLEY MENTAL HOSPITAL.

Applications are invited for the appointment of
an Assistant Medical Officer in the Board's
service at the above Mental Hospital, at a com-
mencing salary of £150 per annum, rising by
annual increments of £25 to a maximum of £450,
together with emoluments (board, apartments and
laundry), valued at £120 per annum. The Board
will allow an extra £50 per annum to the suc-
cessful candidate who (while on this scale) holds
or obtains the Diploma in Psychological Medicine,
for which this Hospital affords special study
facilities.

It will be an advantage if candidates have had
at least one year's experience in general medicine
after qualification.

The appointment is subject to the provisions of
the Asylum Officers' Superannuation Act, 1909,
Class I.

Applications, with copies of not more than two
recent testimonials, stating age and full particulars,
to reach the undersigned not later than January 9th,
1939. There is no printed form of application.

ASSISTANTS REQUIRED.—Several good vacancies. Full particulars on application.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

1000 Patients
 need not go
 without NUMOL
 if the doctor considers
 them ~~deserve~~ have
 it

Although NUMOL is an expensively produced article, it is available for everybody and not only for well-to-do people.

Even when it is bought in the ordinary way, it is cheap and economical to use having regard to its small concentrated doses and to its therapeutic properties, but there are schemes in operation to provide for it being available for even the poorest patient.

It can be obtained for Hospitals at special prices packed in Hospital Containers, and it is also available through all Welfare Centres.

In addition to all these schemes, free supplies can be obtained by Doctors for special cases, and half price supplies are available for patients who are not exactly destitute, but cannot afford to pay the ordinary price. Doctors are invited to write for full particulars.

● A TREATMENT FOR CHRONIC ULCERATION OF THE LEG

As an ambulatory treatment for chronic ulceration of the leg, Saltair Elastic Plaster Bandages offer the inestimable advantage of allowing full activity of the limbs. The bandages are made from a specially woven selvedge material which is uniformly impregnated with an antiseptic zinc oxide paste. They are self-adhesive and highly elastic, providing an even surface dressing which will not crease or slip. Incidentally, they prove extremely effective in the following conditions:—

- AN ABDOMINAL-SUPPORT AFTER OPERATION
- A STRAPPING FOR THE BREAST IN MASTITIS

- A-DRESSING FOR MINOR INJURIES, BOILS, etc.

SYNOPSIS OF MEDICINE

By H. LETHEBY TIDY, M.A., M.D., B.Ch., F.R.C.P.

"Consultants who carry 'Tidy' with them on their rounds will find it a never-failing source of accurate information. A full index of over fifty pages enables any subject to be readily found."
—*British Medical Journal*.

"Tidy's Synopsis holds a deservedly high place, not as a short cut to practice or a medical degree, and still less as a substitute for text-books or bedside teaching, but as an almost indispensable aid to both."
—*Lancet*.

SAFE, SIMPLE AND QUICK

Baxter's New Blood Transfusion Set is a completely equipped apparatus for taking and dispensing blood by the indirect method. No danger of contamination and no chance for clotting while blood is being taken into or dispensed from the same sealed container. For storing excess blood, Baxter's Blood Bank Assembly is a useful accessory.

Baxter's Blood Transfusion Set is available in 500 cc. and 1,000 cc. sizes.

THE BAXTER BLOOD TRANSFUSION SET. An apparatus for the indirect transfusion of citrated blood, in which the blood is sealed against contamination from the moment it leaves the donor's vein until it is injected into that of the recipient.

FOOT COMFORT

By wearing
'APTERNA' HEEL-LESS SHOES

These shoes are designed in the common-sense knowledge that the majority of foot troubles are due in large measure to faulty footwear which aggravates the trouble and does not permit the natural exercise and freedom which is essential to foot health.

LANGHAM HOUSE, UPPER REGENT ST., W.1

Charles H. Baber

Any of the common foot ailments mentioned in the above diagram can be successfully prevented and relieved by prescribing the correct series of "Apterna" Heel-less Shoes.

"Apterna" Shoes are available for men and women and children.

Typical Photos of posture correction. Picture of 15-year old girl before and immediately after the application of the Spencer Corrective Support. Interval of a few minutes between pictures Nos. 1 & 2.

Showing Front Fastening.

The value of Spencer Supports in correcting posture has long been recognised by thousands of doctors who use them regularly.

When we improve posture through a Spencer Corset or Support, we call this **INDIVIDUAL DESIGNING**. Each Spencer Support is designed to meet the individual needs of the patient, from complete measurements and figure-description taken by a trained Corsetière.

The Spencer, either the Belt or the Supporting Corset, is designed in two sections, to give adequate abdominal support and uplift, and correct back support.

SUPPORTS FOR

Maternity
Enteroptosis

Movable Kidney
Sacro-iliac Strain

Hernia
Post-operative

Pendulous Breasts
Pendulous Abdomen

BEWARE OF SUBSTITUTION.—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support, a corset of another make has been substituted, and, because its makers do not understand the Spencer principles of individual designing, has been unsatisfactory. Every genuine Spencer Support bears the **SPENCER** Label.

Trained Spencer Corsetières are resident throughout the Kingdom. Name of nearest gladly supplied on request.

A scientifically trained Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

Spencer Supports and Corsets
are never sold in shops.

T_{HROMBIN}-C_{OAGULANT}-M_{AW} DRESSINGS

● FOR THE RAPID CONTROL OF HAEMORRHAGE

T.C.M. Dressings provide a new method of effectively and speedily controlling haemorrhage.

The Dressings are treated with Thrombin-Coagulant-Maw—a stable preparation of Thrombin, the natural clotting agent of blood—which anticipates the formation of Thrombin in normal shed blood so that clotting commences in a few seconds.

T.C.M. Dressings are not expensive, they cost, in fact, only a trifle more than ordinary Dressings, but one of these dressings will do the work of perhaps several ordinary dressings, thus proving cheaper in the end and saving you valuable time.

The Dressings are supplied sterile, in sealed drums, ready for use. The series consists of Wound Dressings, Lint Squares, and Lint and Plaster Dressings.

Thrombin-Coagulant-Maw is supplied also in Powder form.

Prepared for the mouth and throat

'Dettolin' is specially made to kill quickly the micro-organisms concerned in affections of the mouth and throat. It contains, among other ingredients, the active germicidal principle of 'Dettol'—the modern antiseptic. For all its high germicidal efficiency, 'Dettolin' is soothing and gentle on delicate tissue. It has the added advantage of being distinctly pleasant to use, an important factor when frequent and regular gargling is prescribed.

'Dettolin' is obtainable from Chemists and Medical Suppliers.
Price 9d. and 1/3. Sample, and full information on request.

CREODYNE

(DUNCAN)

A palatable preparation of Lacto-Creosote, Codeina, Aconite, etc., specially suited for affections of the respiratory organs: Chronic Bronchitis, Coughs, Catarrh, etc., etc.

MIST. VALERIAN SEDAT.

(DUNCAN)

A well-blended preparation of Scotch-grown Valerian in combination with Bromide, Hyoseyamus, etc. Indicated in the treatment of Hysteria or whenever a nerve sedative is required.

In bottles of 4, 8, and 16 fluid ounces.

'A.B.' PROTAMINE INSULIN

BRAND (with zinc) SUSPENSION

The absorption of insulin injected in the form of 'A.B.' Brand Protamine Insulin (with Zinc) Suspension is much prolonged and closely resembles the natural secretion of the pancreatic islets. This insulin has a steady action and exerts a better control than that of ordinary insulin over the carbohydrate metabolism. The number of injections can be reduced, a lower total dosage is usually necessary, and the subjective symptoms of diabetes markedly improve.

40 units per c.cm.
5 c.cm. (200 units) 2/4
10 c.cm. (400 units) 4/6

80 units per c.cm.
5 c.cm. (400 units) 4/6

INSULIN 'A.B.' was the first British insulin offered commercially to the medical profession, and has a world-wide reputation for its strictly safeguarded sterility, its carefully standardised strength, its freedom from toxic reactions and its stability in hot climates.

Full particulars will be sent free to members of the Medical Profession.

MANDECAL

(Compound Calcium Mandelate B.D.H.)

In the delicate or hypersensitive patient there is a risk of producing nausea by the administration of ordinary mandelic acid preparations. This risk is reduced to a minimum if Mandecal is employed.

Mandecal is a pleasantly-flavoured, readily miscible powder; it is acceptable to the most fastidious patients.

Clinical trials have established that Mandecal is thoroughly efficacious in the treatment of infections of the urinary tract.

To establish a strong positive Iron Balance

IDOZAN

Idozan contains 5 per cent. assimilable iron. It is non-constipating and acts in fact as a mild aperient. Idozan is a neutral solution, and exerts no harmful effect on the teeth. A tablespoonful three times a day provides the patient with a daily intake of 2.25 grams of pure iron, and thus establishes, without contra indications, a strong positive iron balance.

Idozan is now made in England, and is regularly prescribed by doctors in no less than fifteen different countries.

IDOZAN

The most extensively prescribed iron preparation in the World.

Packings: 4 oz., 8 oz., 40 oz., and 80 oz. bottles.

This is the formula:

| | |
|---------------------------|-----|
| Colloidal Iron Solution.. | 84% |
| Pure Alcohol | 5% |
| Sugar | 10% |
| Flavouring | 1% |

"ALOCOL"

Colloidal Hydroxide of Aluminium

Rational Antacid Therapy

A PART from those cases due to actual organic disease, the treatment of the syndrome of symptoms known as indigestion generally resolves itself into an attempt to overcome hypersecretion of acid and to soothe the irritated or inflamed gastric mucosa.

That "Alocol" possesses intrinsic qualities which render it particularly valuable as a gastric sedative and antacid is now well established. Its freedom from the constipating effect of bismuth, the laxative-action of magnesium salts and the gas-forming properties of sodium bicarbonate are especially noteworthy.

"Alocol" forms with the gastric contents a colloidal jelly which has the power of adsorbing free hydrochloric acid. Its markedly soothing effect on the gastric mucosa promptly relieves pain and discomfort. It does not interfere with the normal process of digestion and is free from the danger of "alkalosis."

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

ALASIL

Safe Salicylate Therapy

THE popularity of acetyl-salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non-narcotic analgesics available. Too often, however, its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

"Alasil" provides the beneficial therapeutic effects of pure acetyl-salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl-salicylate—the least irritating salicylate compound—with "Alocol," a potent gastric sedative and antacid.

Since "Alasil" is better tolerated than acetyl-salicylic acid its use can be pushed or prolonged to a much greater extent than the latter. "Alasil" is, therefore, an analgesic antipyretic and anti-rheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

A supply for clinical trial, with full descriptive literature, sent free on request.

A typical example of the high nutritive values retained in Heinz Strained Foods. (Figures show percentages on the wet basis)

Vegetable and fruit purées, rich in mineral salts, vitamins and other soluble nutriment, constitute the perfect diet for infants and cases of nutritional anaemia.

But despite the wide approval shown by physicians, and a growing appreciation of this dietary by mothers, progress has hitherto been slow, owing to the practical difficulties encountered in home preparation.

The use of vegetables not truly fresh, mechanical losses through oxidation when boiling, and inefficient sieving out of the harsh fibres, inevitably impair the quality of the home-produced preparation.

Now, with the marketing of a range of strained foods by H. J. Heinz Co. Ltd., vegetable and fruit purées containing all necessary dietetic values are available in convenient bulk and form.

Heinz Strained Foods are prepared with all the advantages of the best factory method. The vegetables are specially grown in those areas where soil and climate combine to produce the best; they are harvested when they are just right, and cooked within a few hours of being garnered.

First, the ingredients are scrupulously cleaned. Cooking by light steam pressure in vacuum containers follows, leaving the contents perfectly disposed for comminution by extrusion, and at the same time ensuring retention of the essential juices and mineral constituents. Fine sieving having removed all fibres of a harsh or irritant nature, the purée is then adjusted to an acceptable consistency and sealed in vacuo, the sealed containers being immediately subjected to sterilization under constant conditions of time and temperature.

The purées thus offered are uniform, convenient and of the highest possible nutritive content.

NOTE: Glass containers are not used owing to the deleterious effect of light on the value and palatability of the purées.

THE ADVANTAGES OF COD LIVER OIL

as a reliable source of

VITAMIN A and VITAMIN D

In view of the widely varying vitamin content and origin of many liver oils available to the public, it is interesting to note that the British Pharmacopoeia in their most recent addendum (1936) lay down a definite standard of vitamin content for cod liver oil, and also a definite dosage.

The vitamin content is standardised at not less than 600 International Units of Vitamin A and not less than 85 International Units of Vitamin D per gramme; and the dosage is given as a minimum of 15 minims (a quarter teaspoonful) three times a day. The oil itself is described as "from the fresh liver of the cod."

'SevenSeaS' Cod Liver Oil is extracted on the boat, within thirty minutes of the fish being taken from the sea. It is therefore fresh and easily digested. It is an interesting point of fact that the process of extraction on the boat is impossible with other fish liver oils. 'SevenSeaS' therefore obviates any need to resort to other liver oils made from stale and rancid livers.

In its Standard form, 'SevenSeaS' is guaranteed to conform to the standard

vitamin content laid down by the British Pharmacopoeia. For practitioners wishing to administer Vitamin A and Vitamin D in cases where a large fat intake is contra-indicated, 'SevenSeaS' in its 'High Potency' form has a special significance. The vitamin content of this 'High Potency' oil is guaranteed to be four times the Pharmacopoeia standard, and the dosage can therefore be reduced to a few drops only. This is not a fortified oil, but is obtained simply by selection from the oils of the richest cod livers.

All 'SevenSeaS' Cod Liver Oil is tested and packed in strict conformity with British Pharmacopoeia requirements. Samples of the High Potency Oil, the Standard Oil, and the High Potency Oil in Capsules, will be supplied on request.

GLYCURRANT COUGH LINCTUS

is a new expectorant and sedative preparation, particularly suited to dry coughs, such as that of chronic bronchitis. Its carefully planned composition includes the juice of ripe black currants, an agent which is well known for its soothing effect on the pharynx, and which gives a distinctive, delicious flavour to the mixture.

In bottles at 1/6 and 2/9

Descriptive literature and clinical trial sample will be sent on application.

Chilblains...

COLLOIDAL CALCIUM WITH OSTELIN. Prices (except Eire): Boxes of 6×1cc. ampoules, 5/-; 12 ampoules, 8/6; 30 cc. bottles, 10/-

★ OSTOCALCIUM TABLETS
Prices (except Eire): Tins of 50, 2/3; 100, 4/-; 500, 10/-; 1,000, 17/6. All G.L. prices are subject to usual professional discount.

PRODUCTS OF THE
GLAXO LABORATORIES

The subcutaneous injection of Colloidal Calcium with Ostelin (5,000 international units of vitamin D and 0.5 mgm. of colloidal calcium per cc.) is almost a specific for chilblains. By this treatment even habitual sufferers can be helped through the winter in comfort; and in quite severe cases the skin circulation can be brought to a normal state. Frequently the pain, irritation and swelling subside after the first injection. The usual procedure is to give 2-3 injections of 1 cc. at 3-day intervals; but in chronic cases 6 such injections may be needed.

★ Prolonged treatment should include the oral administration of calcium, by means of the highly assimilable Ostocalcium Tablets, each containing $1\frac{1}{2}$ grs. of calcium sodium lactate and $2\frac{1}{2}$ grs. of calcium phosphate with 500 international units of vitamin D.

Other G.L. products completing the range of modern Calcium therapy

LEVU-CALCIN

Levu-Calcin is a sterile aqueous solution of the calcium salt of levulinic acid, for parenteral use in all conditions needing urgent calcium therapy. The solution is stable. It has been used with marked success in pre- and post-operative treatment for preventing hæmorrhage; inflammatory and allergic conditions with exudation; and hepatic insufficiency; in urgent cases it should be given intravenously; otherwise intramuscularly or intravenously; whichever is more convenient.

Levu-Calcin. In boxes of 3×10 cc. (10%) 3/9, and boxes of 6×2 cc. (15%), 5/-
Prices (not applicable in Eire) subject to usual professional discount.

OSTELIN LIQUID

A suspension of crystalline vitamin D, completely miscible with water. It ensures assimilation of all mixtures containing calcium or phosphorus. It is prescribed for the treatment of rickets and delayed dentition; to help sustain normal skeletal development, and in conditions needing a vitamin D supplement. Each cc. contains 5,000 i.u. of vitamin D.

HIGH-POTENCY OSTELIN

The use of vitamin D in exceptionally high dosage has been advocated by several clinical workers. Although too early for any final statement to be made on its full scope and indications, massive dosage of vitamin D has been used with marked effect in parathyroid tetany, chronic arthritis and rickets. Each tablet contains 50,000 international units.

Ostelin Liquid. $\frac{1}{2}$ -oz. phials, 2/6; 2-oz. bottles, 7/6; 4-oz., 12/6; 8-oz., 22/6. High-Potency Ostelin. In bottles of 25 tablets, 5/-; 100, 17/6.

Prices (not applicable in Eire) subject to usual professional discount.

MODERN VIEWS IN THE PREVENTION OF TUBERCULOSIS*

BY

D. M. DUNLOP, M.D., F.R.C.P.ED.

Physician, Royal Infirmary, Edinburgh

It is a commonplace that in the majority of Western European countries and in North America the mortality from tuberculosis has been declining for many years. Stated concisely, the death rate from tuberculosis in England and Scotland has fallen in the last fifty years by about 75 per cent. Moderately reliable tuberculosis mortality statistics began for the first time to be available coincidentally with Koch's discovery of the tubercle bacillus, which discovery set on foot the campaign against the disease. The decline in tuberculosis mortality thus became apparent at much the same time as the antituberculous measures were initiated, and since then the fall in the one has run parallel with the development of the other. It was natural enough, therefore, for many to believe, and to continue to believe, that this gratifying decline in tuberculosis has been almost entirely due to the noble campaign which has been waged against the disease, largely inspired in this country by Sir Robert Philip fifty years ago. There is much evidence to suggest, however, that the tuberculosis mortality had been declining for many years prior to the special measures taken to combat the disease. Indeed, it is probable that the death rate from tuberculosis had been decreasing in this country since the early part of the nineteenth century. It is, however, apparent that as we go backwards in time an increasing death rate from tuberculosis cannot have continued indefinitely; otherwise everyone would have died of tuberculosis a few hundred years ago, which we know not to have been the case. It has thus been suggested, with considerable evidence for the assumption, that we are at present at the end of a protracted epidemic of tuberculosis, and that the disease is subject to the same epidemic waves as measles, scarlet fever, and diphtheria, with this difference, that whereas the epidemic waves of these latter are relatively short, that of tuberculosis may last a hundred years or more, which is only fitting in a disease which may continue for the lifetime of an individual, in contrast to those which only affect him for a few days or weeks. Further, it is probable that during the course of such an epidemic those nations which have been particularly exposed to the infection have acquired a strong resistance to it, and that those individuals who are peculiarly susceptible to the tubercle bacillus have died at an early age, leaving relatively few descendants who may have

inherited their particular susceptibility. Lastly, the number of young people alive to-day in proportion to the number of people over 40 is relatively less than was the case in the Victorian age, and it is well known that tuberculous disease, particularly where females are concerned, reaches its most lethal peak between the ages of 25 and 35. Thus the decline in tuberculosis mortality may to a large extent be due to circumstances over which we have no control—to the fact that, being on the down grade of an epidemic curve, the seed of tuberculosis is less common than formerly, and that this seed has a proportionately smaller number of susceptible persons on which to produce its effects.

Whether or not we believe that these are potent factors in producing the fall in tuberculosis mortality, it should not lead to a fatalistic attitude in regard to the preventive aspects of the disease. There is no reason to believe that an epidemiological curve cannot be modified beneficially by human efforts. No one, for example, would suggest that the worst effects of epidemics of acute infectious diseases cannot be ameliorated by popular education, by social and public health measures, and by the private efforts of medical practitioners. The same can be said of tuberculosis. The recognition of the fact that we may not be able complacently to congratulate ourselves that the whole fall in tuberculosis mortality has been due to antituberculous measures does not justify the opposite extreme, now adopted by some—to sneer at the great efforts which have been made to combat the disease, or to deny that these have been a potent contributory factor in lowering tuberculosis mortality. We have only to look, for example, to the increase of tuberculosis in Germany during the war, to its great incidence in certain trades, to its wide occurrence in districts smitten by poverty and unemployment, and to the virtual absence of glandular and bone and joint tuberculosis in countries with a clean milk supply, to be certain that epidemiology, immunity, and natural selection are not the only factors in this great problem.

Factors Leading to Tuberculosis

The factors contributing to the spread and morbidity of tuberculosis are many, but the essential cause is, of course, contact with the infecting agent from either the human or the animal source. It therefore becomes of interest to inquire to what extent such infection can or

* Read in opening a discussion in the Section of Tuberculosis at the Annual Meeting of the British Medical Association, Plymouth, 1938.

should be avoided, and whether attempts to prevent infection should occupy an important place in antituberculosis measures. The answer to this question depends to some extent on whether adult exogenous infection occurs with significant frequency in civilized communities. I would suggest that adult tuberculosis usually occurs as a late visceral manifestation of an earlier disease, just as general paralysis is a late visceral manifestation of syphilis, and that it is exceptional for an adult to develop tuberculous disease as the result of an outside superinfection, protected as he is by tubercle bacilli acquired in childhood. As one German writer had it, adult tuberculosis is the last verse of the song, the first verse of which was sung to the infant in its cradle. Occasionally a rather high rate of tuberculous morbidity has been shown to occur among medical students and nurses as the result of professional contact with cases of open tuberculosis. Heimbeck has pointed out, however, that this excessive morbidity is found only among those probationers and students who give a negative tuberculin test on starting training, and who are thus to some extent comparable as regards susceptibility to tuberculosis to the Red Indian when first brought in contact with white men. No doubt this immunity in tuberculinized adults to exogenous tuberculous reinfection may occasionally disappear, just as it occasionally disappears in the case of the common exanthemata. No doubt also it may be temporarily in abeyance as the result of one of the acute infectious fevers like measles, or during the puerperium. At such times a massive exogenous infection may cause tuberculous disease; but such accidents are exceptional, and in the great majority of cases it is as hard to reinfect a previously tuberculinized adult as Koch found it to reinfect a tuberculous guinea-pig. How else can one explain the fact that cases of tuberculous adenitis in sanatoria are not superinfected by cases of open tuberculosis in the same ward; that those most cautious corporations—the insurance companies—do not see fit to load the premiums of tuberculosis officers; and, above all, that there is no statistical evidence to suggest that the tuberculous husband infects his healthy consort with any frequency, or vice versa?

Primary Infection in the Child

If it be true—and there will be many to deny it—that a tuberculinized adult is not usually susceptible to a secondary exogenous infection, the attempt to prevent infection in adults is not a matter of primary importance. Our efforts should rather be directed to the prevention of massive primary infection in the young child, who, like the savage, forms virgin soil for the tubercle bacillus. It is probable that some 40 per cent. of children who show a positive tuberculin reaction before the age of 2 die from acute tuberculosis before reaching the age of 5. It is highly desirable, therefore, that infection with tuberculosis should be delayed as long as possible, since it would seem that the younger the child when infection occurs the more likely it is to develop lethal disease, the result of the infection. It would seem, from the results of tuberculin tests, that in this country the tuberculinization of the community is on the average occurring at a later age than heretofore, and this is all to the good.

In the absence of sufficient proof as to the efficacy or harmlessness of the B.C.G. vaccine—and its possibilities might be explored more fully in this country than they have been—efforts to prevent massive infection in young children must continue to be directed along two main channels: their segregation from close contact with cases of open tuberculosis, and the provision of a clean milk

supply. These two measures, if effectively carried out, would go far in themselves to diminish child mortality and morbidity from tuberculosis. They would in my opinion go further: they would tend very considerably to reduce the pulmonary tuberculosis and other late visceral manifestations of the disease in adult life, since experience shows that such manifestations occur very frequently in adults who were subjected to repeated massive infections in childhood.

The segregation of young children from close and continuous contact with open cases of tuberculosis in their family is a matter of great difficulty. The chief ways in which the risk of infection from the human type of the bacillus in a child's home life can be prevented, or reduced to a minimum, are by the removal to a residential tuberculosis institution of an open case of tuberculosis among the parents or those living in the house, or by the removal of the child from the tuberculous home. The second method, or Grancher system, is practised to a considerable extent in France. It aims at bringing up the child in an institution where it will lead a healthy life, no longer exposed to the risk of massive infection. The objection to it is that it interferes with the continuity of the child's home life, and though it is practised to a limited extent in this country, it seems an impossible ideal, and one that it is perhaps undesirable to adopt universally. It is much more satisfactory to remove and treat the adult patient who is the potential source of the infection. With the limited number of beds at our disposal in tuberculosis institutions even this is at present a counsel of perfection. In many districts more beds for tuberculous patients are urgently needed, and in a few cases medical officers of health and tuberculosis officers are too ready to comply with the natural desire of the local authorities to reduce the rates at the expense of adequate accommodation. It is doubtful if any physician in the public health service does his duty adequately unless he is being a continual nuisance to his committee in this respect. No doubt, also, many beds are occupied by patients who might well be nursed at home without detriment to themselves or any risk of infecting young children. Lastly, patients are often inadequately informed of the risk of infecting their children. When this is carefully and considerably explained, it is very rare for them to refuse segregation, however painful such segregation may be.

Infection from Milk

If the segregation of the young child from massive human infection is a matter of extreme difficulty, its segregation from massive infection through milk is eminently practicable. As the result of researches by Griffith, Munro, and others, there is no doubt that bovine type tuberculosis is responsible for a considerable percentage of tuberculous morbidity among children, particularly in Scotland; and though the bovine type of disease is mostly to be found in glandular, lupoid, abdominal, bone and joint, and meningeal lesions, yet it may on occasion cause any type of tuberculosis—not even excluding the pulmonary variety. Having regard to the great prevalence of tuberculosis among the dairy herds of this country, and the absence of a national plan for dealing with it, it is clear that, if conditions are allowed to remain as they are, large numbers of children are doomed to die of bovine tuberculosis or to become crippled by it. In several countries of the world, notably America and New Zealand, bovine tuberculosis has been largely eradicated, owing to the measures adopted to ensure a clean milk supply; but large quantities of tuber-

culous milk are still consumed in this country. As Griffith says, "It is hardly too much to say that if bovine tuberculosis in the human was as distinct clinically from tuberculosis caused by human bacilli as, say, diphtheria is from tonsillitis, public opinion would long ago have insisted on the eradication of tuberculosis in the bovine animal—a perfectly feasible proposition given the necessary dictatorial powers." It is common to hear the remark that a child is all the better for being immunized by a small dose of bovine bacilli. Unfortunately one cannot regulate the dose, and no one would be so bold as to suggest that it is good for a child to drink a teaspoonful of tuberculous pus in its milk.

The provision of a clean milk supply would involve extensive legislative measures and considerable expense. The effort and expense involved, however, would be a fraction of that being at present very necessarily undertaken in rearmament, and would be a productive rather than an unproductive expenditure. It is perhaps not too much to hope that when men have learnt to beat their swords into ploughshares this problem will be seriously tackled.

To those obsessed by the difficulties of the problem of providing a clean milk supply the following postulates, which are accurate enough for all practical purposes, may be put forward for their consideration; any cow giving tuberculous milk to-day will be dead within a year; any cow affected with tuberculosis to-day will be dead in five years; almost every cow which will be giving milk in 1944 is either yet unborn or will be still free from tuberculosis.

Until the ideal of a national clean milk supply is achieved it seems only common sense that all milk given to young children should be pasteurized. It is true that this method is not 100 per cent. efficient in preventing the occasional occurrence of tubercle bacilli in milk, and that in the process certain insignificant losses occur in the milk in respect of its vitamin and mineral content. No one, however, with any knowledge of the subject can believe that these drawbacks do not pale into utter insignificance in comparison with the great risks which are run by children in consuming unpasteurized milk from herds that have not been tuberculin-tested.

Having, by segregation and by the provision of a safe milk supply, taken measures against the massive contamination of virgin soil, the factors that conduce to tuberculous disease must be looked for, not so much among the seed as in the soil in which the seed is sown. That is, infection is almost certain to take place—ideally in small and infrequent doses—and thereafter all our efforts should be directed not so much to the prevention of infection as to raising the resistance of the infected individual, particularly the young adult, against the infection becoming a disease.

Raising the Resistance

Apart from the question of race and breeding, over which we have no control, the resistance of an individual to his tuberculous infection will depend very largely on certain environmental conditions: housing, nutrition, habits, and intercurrent infections.

One has only to glance at the innumerable statistics produced from all over the world to see that tuberculosis and overcrowding go hand in hand—the death rate in many cases running almost exactly parallel to the extent of the overcrowding. The aetiological relation of overcrowding to tuberculosis has, however, been somewhat difficult to resolve into its component parts. On the one

hand, tuberculosis may have a profoundly deleterious effect on the earning capacity of an individual household, causing an excess of tuberculous families to live in poverty-stricken circumstances; on the other, overcrowding itself, with its concomitant inferior nutrition, may act by favouring contact infection and by reducing the resistance of the individual to the disease. As the result, however, of the Tyneside inquiry, recently undertaken by Bradbury at the instigation of the National Association for the Prevention of Tuberculosis, it would seem quite definite that overcrowding *per se* is an extremely important causal factor in tuberculosis, though its relative importance will depend to some extent on the nature of the other adverse conditions present. Overcrowding is a factor which is capable of elimination in the course of time, and the problem is being steadily tackled in this country. There is every reason to believe that the better housing of the future will cause a marked diminution in the incidence of the disease.

Undernourishment as a Factor

If, on the other hand, good environmental conditions as regards housing are only obtained at the expense of increased rents, and therefore cause reduction of the family's food-purchasing power, the advantages which accrue from good housing may be considerably outweighed by nutritional depreciation. This was shown quite clearly in some well-controlled observations by McGonigle in Stockton-on-Tees, where the death rate from tuberculosis actually rose in a new housing area. The increased rate could be definitely correlated with a diminished expenditure on food as the result of increased rents. Again, from Bradbury's Tyneside inquiry, and from numerous other well-controlled observations, a definite statistical association can be traced between tuberculosis and undernourishment. It appears that tuberculous families, while eating more bread, consume less meat, less butter, and particularly less milk than non-tuberculous families. Up till now the principles of good nutrition and the subject of dietetics have been largely neglected in the medical curriculum, and while every doctor can prescribe bottles of medicine comparatively few can prescribe detailed diet sheets. It is not surprising, if ignorance, or lack of enthusiasm, on the subject of nutrition is common in the medical profession, that it should be even more common in the general population; and it is almost certain that a great educational campaign on the subject of nutrition, particularly among girls and young women, would be far more conducive to national physical fitness than the less prosaic campaign now being waged on the subject of playing-fields. At the same time there is nothing more annoying than to hear well-fed people arguing that the deficient diets of the poor are entirely due to their ignorance of what are the best foods to buy. As Sir John Orr has shown, it would tax the skill of the most competent dietician to provide entirely adequate diets in respect of first-class protein, vitamins, and minerals on the income of many of our working-class families. Still, progress is being made in this field also, and the population as a whole has probably never been so well fed as it is to-day. This progress is likely to be expedited when money becomes available for the saving of life rather than for its destruction. One of the most important pieces of public health legislation of recent years took place when milk was made more generally available for school children. The Minister responsible for that measure was then only the Minister for Agriculture; now that he has become Minister of Health even greater things may be expected.

Training in Tuberculosis

It is apparent that preventive measures taken against tuberculosis can never hope to be entirely successful without the active and intelligent co-operation of all those engaged in the practice of medicine. It may be questioned whether in many medical schools the doctors of the future are being adequately trained in the broader aspects of tuberculosis and in its clinical manifestations. Now that tuberculous cases have been almost entirely removed from the general teaching hospitals and relegated to special institutions, the training of the average medical undergraduate in tuberculosis is too often limited to an occasional visit to a chest clinic or a chest hospital. Here he is given the opportunity of examining a few patients suffering from advanced fibroid disease who are usually called "good teaching cases," and of listening to the sighing of amphoric breath sounds to the accompaniment of consonating crepitations and crack-pot notes—archaic physical signs of little vital clinical importance. It would be just as sensible to teach syphilis only by the demonstration of cases whose knee-jerks were absent and whose pupils had long since failed to react to light. Over-emphasis is laid on physical signs in the chest, which are often difficult or impossible to elicit in early pulmonary tuberculosis, whereas too little instruction is given on the general signs of tuberculous intoxication, common to all forms of the disease, which are often apparent to the patient's relatives and friends but overlooked by the doctor obsessed by his hunt for crepitations in the lungs. Again, the significance of history-taking in the diagnosis of tuberculosis is often insufficiently stressed; and yet the vast majority of patients repeat with variations the same history with the regularity of a theme in a symphony. In many medical schools, in short, the student is not educated in the natural history of tuberculosis, and he graduates with the idea that a slight knowledge of percussion and auscultation is sufficient equipment to enable him to grapple with the disease.

It is not surprising under these conditions that most cases are far advanced before they are diagnosed, and that meanwhile the patients may have grossly infected the youthful members of their family; that patients in need of complete rest, and perhaps collapse therapy, are simply advised to take a holiday in the country, or to change their occupation—from a sedentary one like that of a clerk to a strenuous one like that of a chicken farmer; and that the segregation of young children from open cases of tuberculosis is too often neglected even in circumstances where it is perfectly practicable.

I am only too conscious that there is nothing new in the foregoing remarks. Their object has been to focus discussion on some of the more important questions confronting those working for the prevention of tuberculosis. Owing to lack of time, certain subjects have not even been touched upon. It is generally recognized, for instance, that the open-air school is invaluable in raising the resistance of the delicate child to the disease, and it might be questioned why his more healthy brother should not share in its advantages. Again, the prevention of certain diseases which strongly predispose towards tuberculosis, such as silicosis, might be discussed. Lastly, the thorny problem of contact examination will doubtless find strong protagonists on either side. On the one hand its difficulties and impracticability may be stressed; on the other it may be claimed that contact examination, in its widest sense, is among the most important functions of the dispensary in the prevention of tuberculosis. With the latter view I cannot too strongly agree.

FOUR CASES OF WEIL'S DISEASE INFECTED FROM THE SAME STREAM

BY

KENNETH M. ROBERTSON, M.D., M.R.C.P.

*Honorary Physician, Royal Hampshire County Hospital,
Winchester*

Weil's disease is still rare enough in this country to make its diagnosis difficult unless the clinical manifestations are familiar and its possibility is borne in mind. It is a disease that is admittedly serious, and must threaten life whenever it appears. Different writers have recorded a mortality varying from 10 to 50 per cent. of all cases.

Specific treatment in the form of antiserum is available, and may be of great value, especially if administered in large doses and early in the disease. Davidson and Campbell (1934), in reporting a series of cases from Aberdeen, came to this conclusion: "Hence it appears to us that the clinical diagnosis in the early stage, before jaundice occurs, presents almost insuperable difficulties. Accordingly, the full benefit of serum treatment is unlikely to be realized."

During the past two years it has been my good fortune to have seen and treated four cases of leptospirosis. In addition to these I have had under my care, and have investigated, three other possible but unproved cases. The experience gained by the study of each individual case, as it has appeared, has made possible the early diagnosis and treatment of the later cases, with, I maintain, the most satisfactory results.

The diagnosis should escape no one when jaundice, associated with nephritis and nitrogen retention, has followed upon an acute febrile illness in which headache, severe muscular pain, and scattered haemorrhages have been well marked. But all writers are agreed that at least 50 per cent. of these cases never do become jaundiced, while to wait for a laboratory diagnosis before starting serum treatment is to endanger the patient's life.

I feel, however, that in the very earliest stages the clinical picture is suggestive enough to make justifiable the use of serum before the diagnosis can be proved. Sudden onset of a severe illness, with headache, and quite frequently meningeal signs, high fever, severe pain, and great tenderness in the limb muscles; haemorrhages from the nose and the gastro-intestinal and urinary tracts; and a most characteristic watery suffusion of the conjunctivae such as I personally have never seen in any other condition—these well-marked and very characteristic features should make it possible for the condition to be suspected. If in the presence of these symptoms and signs there is the history of a possible source of infection to which the patient has recently been subjected, as indeed there was in each of the proved cases here described, serum treatment should be instituted at once, without waiting for the laboratory to confirm the diagnosis. The very fact that all these cases—so far as I can discover the only cases of this particular infection that have been reported from South Hampshire—should have come under the eye of one practitioner would suggest that cases are occurring and are not being recognized, and that a fuller and wider knowledge of the infection and of its manifestations would bring to light other cases with, one would hope, a shortening of illness and even a saving of life. It is with this end in view that these cases are here reported in full.

Case I

A healthy boy aged 15 complained of headache on the morning of Saturday, July 18, 1936. His temperature was 101°. Throughout the day his condition deteriorated: headache became more severe, and he vomited. By evening his temperature was 103°. During the night he became violently delirious. On Sunday morning Dr. G. B. Wainwright asked me to see him. His temperature was 104° and pulse 94. Restless and complaining of severe headache, he had all the appearances of being seriously ill. It was noticed that his conjunctivae were suffused, and the possibility of a measles infection had been considered. The only other physical signs were those of severe meningeal irritation, a strongly positive Kernig's sign, and neck rigidity. Lumbar puncture was carried out at once, and the fluid, which was under pressure, appeared clear, and was in fact found to be perfectly normal. The boy's headache, which had been relieved by lumbar puncture, returned later in the day, and his meningeal signs tended to increase, so that a further specimen of cerebrospinal fluid was obtained in the evening, but with precisely the same findings.

He was seen on Monday evening by Dr. Gordon Holmes, by which time his meningism had disappeared, and the only findings were a temperature of 103° and absent deep reflexes. In considering the possible diagnosis Dr. Holmes suggested a deep-seated pneumonia, but mentioned that some cases of Weil's disease had been described which had an onset such as had been noted in this case.

For the next three days the patient remained very ill, with raised temperature, headache, and now very severe pain in the muscles of his legs and forearms. There had also been several small epistaxes.

On Thursday evening—the fifth day of his illness—slight conjunctival icterus was noted, while his urine was found to contain bile and albumin. He was seen by Dr. Hamilton Fairley next day, by which time his jaundice had deepened. The diagnosis of Weil's disease was confirmed on clinical grounds, and 40 c.cm. of anti-leptospiral serum was injected intravenously. Dr. Fairley took blood and urine with him to London, and later reported the following findings: "Van den Bergh—positive direct reaction, biphasic, 22 units; blood urea—106 mg. per 100 c.cm.; blood count—white cells, 10,300 (91 per cent. polymorphonuclears). The blood serum gave a positive agglutination reaction, 1 in 3,000 dilution; the urine contained albumin, granular casts, bile salts, and bile pigments."

Twenty c.cm. of serum was injected into muscle on each of the next three days, during which time, though the jaundice deepened, the patient's general condition improved steadily; his temperature was normal by the tenth day. Details of the changes in his blood chemistry are given in Table I.

TABLE I.—Changes in the Blood Chemistry in Case I

| Date | Van den Bergh | | Blood Urea |
|---------|---------------|----------|------------|
| | Direct | Indirect | |
| 24/7/36 | Biphasic | 22 units | 106 mg. |
| 27/7/36 | " | 56 | 88 mg. |
| 3/8/36 | Delayed | 7.5 | 29 mg. |

During the third week of his illness there was a rise of temperature up to 101°, and this was accompanied by swelling and extreme tenderness of the right parotid gland. So severe did this condition become that the gland was incised under nitrous oxide, and, though no pus was obtained, tension was relieved and the condition rapidly subsided. The boy remained jaundiced for about five weeks, and after a long and rather tedious convalescence made a complete recovery.

This patient, a keen swimmer, had been bathing throughout June and July in a swimming-pool through which runs the River Ichen. It was known that from time to time rats gained access to this pool.

Case II

Some twelve months or so later another healthy boy of 14 became ill. This boy had also often swum in the same bathing-pool as had Case I, but on account of a fractured metacarpal bone he had not done so for ten days preceding the onset of his illness. He was seen on Monday morning, July 26, 1937, by Dr. Wainwright, who found him then in perfect health and pronounced his hand as healed. He was taken suddenly ill the same evening with fever, headache, and epistaxis. His temperature rose to 103°, and on the next day he complained of abdominal pain, which was followed by a melaena stool. I was asked to see him on the evening of July 27, when I found this condition: temperature 102.8°, pulse 96, well-marked conjunctival suffusion, dried blood about the nose and mouth, and signs of meningeal irritation. His headache was relieved by lumbar puncture, when a pathological fluid was obtained. The various laboratory findings are given in Table II.

TABLE II.—The Laboratory Findings in Case II

| Date | Day | V.C.B. | C.S.F. | | | Urine | B.U. | White Count | Serum Reaction |
|---------|-----|----------|--------|------|-------|--------------------------|------|-------------------|--------------------------------|
| | | | Pa | Cl | Cells | | | | |
| 26/7/37 | 1 | Negative | 20 | 6.0 | 6 | Alb. + Casts + Red cells | 95 | 5,100 70% poly | |
| 31/7/37 | 5 | " | 35 | 6.0 | 116 | " | 60 | 8,150 74% poly | +1:10 blood |
| 1/8/37 | 6 | " | 40 | 6.0 | 226 | " | 61 | | |
| 3/8/37 | 8 | " | | | | | | | +1:1,000 blood |
| 6/8/37 | 11 | " | 30 | 6.0 | 6 | " | 36 | | +1:3,000 blood +1:20 C.S.F. |
| 10/8/37 | 15 | | 30 | 7.20 | 4 | Trace alb. only | 55 | | |
| 17/8/37 | 22 | | | | | Trace alb. | 26 | | |

The provisional diagnosis of Weil's disease was made, and serum treatment was begun as soon as the material could be obtained. He had his first dose of serum on Wednesday morning, exactly thirty-six hours after the onset of his illness. He was given 20 c.cm. of serum intramuscularly on Wednesday, Thursday, Friday, and Saturday. During this time, as will be seen from the table, his meningeal condition was deteriorating, while his van den Bergh reaction remained negative. I was not then aware that jaundice was not an essential part of the picture, and I felt obliged to reconsider the diagnosis.

On Monday, August 2, Dr. Hamilton Fairley again came down in consultation, and confirmed the provisional diagnosis upon which treatment had been based. The next day I received a report from Major Brown that this patient's blood serum gave a weakly positive agglutination reaction. This blood had been obtained on the fifth day of his illness.

The boy was given a further 40 c.cm. of serum, and, except for a slight secondary rise in temperature during the third week, made an unusually rapid recovery.

Case III

On Saturday, June 25, 1938, a young man aged 20 was taken ill. He shivered, complained of retrosternal pain, and vomited. The next day he felt better, but was less well again on Monday. I first saw him at 11 a.m. on Monday, about forty hours after his first symptom.

His temperature was 103°, and his only physical signs were an injected throat and suffused eyes. Upon inquiry it was elicited that he had been bathing daily in another swimming-pool through which the River Ichen runs. He was admitted to hospital immediately, and treatment was started as soon as serum could be obtained. His blood chemistry, etc., are shown in Table III. During the next three days he developed extreme tenderness in the muscles of his calves and forearms, while his headache increased. There were several small

haemorrhages from his nose. Serum was given as follows: on June 28, 40 c.cm.; June 29, 40 c.cm.; June 30, 20 c.cm.; July 1, 40 c.cm. The whole of this serum was injected into muscle. His general condition began to improve after the second dose, and on July 2 his temperature was normal.

TABLE III.—*The Laboratory Findings in Case III*

| Date | Day | V.d.B. | C.S.F. | | | Urine | B.U. | White Count | Serum Reaction | Serum Given |
|---------|-----|--------|--------|---------|-------|-------------------------------|--------|---------------------|------------------------|-------------|
| | | | Pn. | Cl | Cells | | | | | |
| 27/6/38 | 3 | — | mg. 30 | mg. 690 | 4 | Alb. ++ Casts Red cells | mg. 50 | 11,600 79% polys | Blood, killed S-pig | c.cm. |
| 28/6/38 | 4 | | | | | | | | Negative 1:20 | 40 |
| 29/6/38 | 5 | + | | | | " | 121 | 7,300 72% polys | | 40 |
| 30/6/38 | 6 | | 30 | 690 | 4 | | | | Positive 1:3,000 | 20 |
| 1/7/38 | 7 | + | | | | Trace alb. | 100 | | | 40 |
| 29/7/38 | 35 | | | | | " | 30 | | | |

Except for conjunctival icterus, which was noted on June 29, there was no clinical jaundice. He was discharged from hospital on July 9—the fourteenth day of illness—being quite free from symptoms. On July 21 he complained of pain in the neck and headache, and his temperature rose to 102°. In forty-eight hours this had subsided, and he was in bed for only three days. Since then he has remained well.

Case IV

This patient, a man aged 29, who was employed as a worker in watercress beds some seven miles up the River Itchen, was admitted to hospital on March 7, 1937, with the following history.

On February 27 he had been taken ill, with high temperature, headache, vomiting, and pain in the back. The diagnosis of influenza had been made, and with treatment his temperature had fallen to normal. On March 3 he was noticed to be jaundiced, and this became rapidly more marked. Epistaxis occurred several times, and his urinary excretion became greatly diminished. He was sent into hospital by Dr. Kent with the tentative diagnosis of leptospirosis.

On admission he was apyrexial, had a pulse rate of 90, was deeply jaundiced, and had a very parched dry tongue and old blood about his nose and mouth. Herpes were well marked. The liver was enlarged and there was a purpuric eruption over the trunk. He was quite rational and was able to give a clear account of his illness. He stated that he had passed very little urine for the last three days. A catheter was inserted, and 6 oz. of deeply coloured urine was withdrawn. This contained albumin, casts, and red cells. The white cell count showed a leucocytosis of 15,300, with 85 per cent. polymorphs. The van den Bergh reaction was strongly positive, while his blood urea was recorded as 572 mg. per 100 c.cm. Blood taken on the day of admission—the ninth day of illness—gave a completely negative result to the agglutination test in all dilutions. Serum treatment had been started at once, and 20 c.cm. was injected intramuscularly on March 8, 9, 10, and 11.

Every effort was made to restart his urinary secretion, and he was given continuous intravenous saline, with hypertonic glucose every four hours. Hot packs, an electric cradle, and hot colonic lavage all proved of no avail, and he died on March 12—the fourteenth day of his illness.

The urine was repeatedly examined for leptospirae, but these were never demonstrated. Blood taken the day before his death gave a positive agglutination reaction at a dilution of 1 in 100. Post-mortem examination revealed an enlarged liver in which leptospirae were demonstrated, and small haemorrhages distributed throughout the viscera. A very striking feature of this case had been that, in spite of the

extraordinary figures recorded when the blood urea estimation was carried out, the patient remained able to talk intelligently to within twenty-four hours of his death. His blood chemistry is shown in Table IV.

TABLE IV.—*The Laboratory Findings in Case IV*

| Date | Day | Urine | C.S.F. | | | Blood Count | B.U. | Serum Reaction |
|----------|-----------|--|--------|-----|-------|---------------------|---------|-------------------|
| | | | Pn. | Cl | Cells | | | |
| 7/3/37 | 9 | 6 oz. Bile, alb., casts, red cells, no leptospirae | mg. | mg. | | 15,300 85% polys | mg. 572 | Negative |
| 10/3/37 | 12 | 2 oz. | | | | | 865 | |
| 11/3/37* | 13 | 4 oz. | 45 | 759 | 4 | | 685 | Positive 1:100 |
| 12/3/37 | 14 (died) | | | | | | | |

* On examination at this date the cerebrospinal fluid was found to contain 660 mg. of urea per 100 c.cm.

The three remaining cases were investigated when the possibility of Weil's disease was considered, but in none of them was the diagnosis confirmed in the laboratory.

Case V

A woman aged 55 was admitted to hospital at the end of August, 1937, very deeply jaundiced and with no other physical signs. The jaundice had been present a week, and had been preceded by abdominal pain, vomiting, and a temperature of 102°.

While in hospital she ran a little irregular fever up to 100°. Her urine contained albumin but no casts. Her van den Bergh reaction was strongly positive, while her blood revealed a massive leucocytosis—45,400 white cells (95 per cent. polymorphs). Her blood urea was 554 mg. per 100 c.cm. on admission and rose to 581 mg. on the day before death, four days later. Her serum was completely negative to the agglutination reaction. Post-mortem examination revealed an enlarged liver and scattered haemorrhages, but unfortunately no attempt to demonstrate leptospirae was made. In this case no suggestion of a possible exposure to infection was obtained.

Case VI

A woman aged 25, a telephonist, in whom no history of likely infection could be obtained, was admitted to hospital on May 26, 1938. She had been taken ill ten days before with fever and pain in the back. The fever persisted for four days, and then gave way to vomiting. Jaundice was noticed on the seventh day of her illness. On admission she was very jaundiced and there was a small purpuric eruption over the trunk. No history of other bleeding could be elicited. The liver edge was palpable, but there were no other physical signs. The urine contained albumin, casts, and red cells, together with tyrosine crystals. A blood count showed 9,600 white cells, 74 per cent. being polymorphs. The blood urea was 49 mg. per 100 c.cm. The van den Bergh reaction was positive. The serum reaction was positive in 1 in 30 dilution. The serum reaction was repeated twice at intervals of one week, in the hope of obtaining a rising titre, but it remained completely negative at all dilutions. This patient was never seriously ill, and improved rapidly. Jaundice disappeared in three weeks from the onset. Urine became normal and the blood urea fell. No serum was administered.

Case VII

A boy aged 7 was admitted to hospital in July, 1938. He was slightly jaundiced, and had been ill with fever up to 102° for eight days. His urine contained albumin, casts, and red cells, while his blood urea was slightly raised. His agglutination reaction was negative and blood count normal. His illness was slight, and he made an uneventful recovery. No serum was given. The boy, we were told, had frequently "paddled" in the River Itchen.

Commentary

It will have been noticed that in each of the proved cases an obvious source of infection was recorded. All three boys who recovered were keen swimmers, and had been bathing frequently in water which certainly might have been infected by rats. An unsuccessful attempt was made by the local health authorities to demonstrate infection in rats caught at these places, but it may be significant that, following an attempt to eliminate rats from the first bathing-pool, no further cases have come to light which could possibly have been infected there, while this summer's case occurred as the result of bathing in another pool in the same river. The fatal case, which is chronologically second on the list, but has been described last for convenience, was that of a man who by reason of his employment must often have been exposed to the risk of infection.

The striking difference in outcome and in length of illness which has been estimated in Cases II and III, where diagnosis was made early and serum given at once, as compared with Cases I and IV, where serum was not given until jaundice had appeared, cannot, I think, be regarded as a coincidence. Both the former cases appeared to have a severe infection, as judged by a well-marked meningitis in Case II and the early jaundice in Case III. Indeed, in the latter case it would seem fair to assume that the jaundice was aborted by serum given at once.

Each of the patients I was able to see at the onset of illness had that typical appearance of the eyes which has to be seen to be understood. Once seen it will always be recognized. In Case III one literally made the diagnosis "from the door," so striking was it. The whole of the bulbar conjunctiva appears inflamed, but there is less "anger" than in an inflammatory conjunctivitis and the injection seen in measles, while the slight conjunctival oedema imparts to the whole a watery look. The coloration is more pink than red. This appearance, when present, is evident within twenty-four hours of the onset, and may persist until the jaundice shows. It has been suggested that it may possibly indicate the site of infection in some cases. Schüffner (1934) describes a case in which a laboratory worker was infected by blood accidentally squirted into the eyes. Davidson and Smith (1936) found this appearance in 57 per cent. of their cases. In every case the blood urea was raised to figures that might well be disturbing, while those recorded in the fatal case, No. IV, are higher than I have seen noted elsewhere. Davidson, Campbell, Rae, and Smith (1934) report a blood urea of 349 mg., with death, and Swan and McKean (1935) record blood ureas of 387/600 mg. and 567 mg., both patients dying, while a case in which the blood urea was 285 mg. recovered. In the jaundiced cases the jaundice itself was suggestive, and was a bright yellow, almost orange-yellow. In fact, it was the colour of the jaundice in Case V, which first made me suspect that that patient might be suffering from Weil's disease. Swan and McKean also noted this characteristic of the jaundice, and in describing their cases speak of "intense orange," "bright golden," etc.

The secondary rise of temperature so often described—Schüffner (1934), Davidson and Smith (1936), etc.—appeared in each of the three cases which recovered. Davidson and Smith state that 50 per cent. of their cases showed this feature.

The unusual complication of parotitis which was a feature of Case I must, I think, be associated with the

infection, coming as it did at the time of the secondary rise. Willoughby and Shera (1934) describe this as appearing on the tenth day in their case. J. D. Lendrum (1936) noted the abolition of the deep reflexes in his case; it will be remembered that this was found in Case I. During his convalescence Case III complained bitterly that he was losing his hair. This has frequently been recorded in the past (Fairley, 1934; Lendrum, 1936; etc.).

Leucocytosis with a shift to the left is so often found as to be a valuable point in differential diagnosis from catarrhal jaundice, in which this finding is absent. It was absent in Case II and was not at all well marked in Case III. Maxwell's (1935) case had only 6,600 white cells and a normal differential count.

Case III complained of retrosternal pain at the onset of the attack. This is of interest in that Jeghers, Houghton, and Foley (1935), in the report of the post-mortem examination of their case, record acute oesophagitis.

In Weil's disease the physician looks to the pathologist for proof of diagnosis. That being so, real doubt must be cast upon any diagnosis which does not carry with it confirmation from the laboratory. In order to receive the maximum help from the pathologist we must remember that leptospirae can be demonstrated in the blood stream during the first five or six days of the illness. In Case III blood taken on the third day of illness and injected intraperitoneally into a guinea-pig killed the animal after seven days. Leptospirae were demonstrated in the animal's liver.

The agglutination reaction does not become positive until the fifth or sixth day. In Case II it was weakly positive on the fifth day, while in Case III, negative on the fourth day, it was strongly positive by the sixth.

After the tenth day leptospirae may be demonstrated in the urine. From this it can be seen that laboratory diagnosis is unlikely before the seventh or eighth day of disease, while to withhold serum until this time may well mean disaster.

The agglutination reactions, which were all most generously carried out by Major H. C. Brown, show certain points of interest. The negative result as late as the ninth day in Case IV is unusual. This reaction was positive four days later, and the delay may have indicated an overwhelming infection. In this connexion it seems not unreasonable to suppose that in Case V the negative reaction obtained was not sufficient to exclude Weil's infection. The sudden appearance of a strongly positive reaction in Case III on the sixth day, after a completely negative finding forty-eight hours earlier, might be thought to be due to the large doses of serum given in the interim. In a personal communication Major Brown assures me that this is not the case, and he is supported by Professor Schüffner (1934), speaking of cases treated with serum and later proved not to be suffering from leptospirosis. In these cases the reaction remained negative. None of the cases in the present series gave a positive reaction in dilutions greater than 1 in 3,000, whereas reactions at 1 in 30,000 are often recorded in untreated cases which recover. This is probably due to the use of serum, which, though curative, appears to depress the formation of active immunity in the body (Schüffner, 1934).

The diagnostic value of a positive reaction has been established. Davidson and Smith (1936) carried out the test on some 400 different sera and were unable to detect a single positive result, except in their clinical cases. This should be considered in connexion with Case VI, the serum of which gave a positive result at 1 in 30, which was later not confirmed. Major Brown was unable to

TABLE V.—*The Principal Features of the Four Proved Cases*

| Case and Age | Mode of Infection | Day of Jaundice | Leucocytosis | Blood Urea | Albumin | C.S.F. | Agglutination | Leptospirae | Day of First Dose of Serum | Total Dose | Length of Illness |
|---------------|-------------------|------------------|--------------|------------|---------|-----------------|----------------------------------|---------------|----------------------------|------------|-------------------|
| Male (15) | Bathing | 5th, severe | + | mg. 106 | + | Normal | 1:3,000 7th day | — | 6th | c.cm. 100 | 12 wks. |
| II Male (14) | | None | — | 95 | + | Pleocytosis 226 | 1:3,000 11th day 1:10 5th day | — | 2nd | 120 | 5 " |
| III Male (20) | " | 4th, slight | ± | 121 | + | Normal | 1:3,000 6th day | Blood 3rd day | 3rd | 140 | 4 " |
| IV Male (29) | Watereress work | 5th, very severe | + | 865 | + | Normal | 1:3,000 13th day — 9th day | Liver P.M. | 9th | 80 | (Death) |

explain this finding, and stated that it was unique in his experience. He was inclined to doubt the diagnosis of Weil's disease in this case, though clinically the patient's condition was most suggestive of it. The dosage of serum to be given and the route of administration have never been laid down. From these cases it would appear that, so long as it is given early and in a dose of at least 40 c.cm. a day, it is as effective when injected into muscle as it is when put into the blood stream. It will be seen that the ultimate result and the length of illness are in direct proportion to the day of disease on which the serum is given—four and five weeks of illness in Cases II and III, compared with twelve weeks and death in Cases I and IV respectively. Serum was never used during the secondary rise of temperature, and this always settled without specific treatment.

In addition to specific treatment, which has already been described, it is important to maintain the urinary secretion. With this end in view all cases were treated with a high-carbohydrate protein-free fluid diet. The urine was maintained alkaline with potassium citrate, and, when necessary, glucose saline was given intravenously. The bowels, which tended to be constipated, were kept open with enemata. In Table V the four proved cases have been compared. The salient and important features of their illness have been recorded and the value of early serum treatment has, I think, been demonstrated.

Summary

Four proved cases of Weil's disease are here recorded. Three of these occurred as the result of bathing in one river, while the fourth patient was infected from the same river, in which he worked. The possibility of early diagnosis is stressed, while the need for early specific treatment is demonstrated. Three other clinically suggestive but unconfirmed cases are reported. Certain points of unusual interest about the different cases are discussed.

It gives me great pleasure to record my indebtedness to Major H. C. Brown, who carried out all the agglutination tests in these cases and gave me much invaluable help. I am indebted also to Dr. Hamilton Fairley, whose opinion in Cases I and II was of the utmost value. The remaining laboratory investigations were carried out for me by Drs. Athole Ross and Charles Wrigley, honorary pathologists to the Royal Hampshire County Hospital: my thanks are due to them. I am very grateful to my partner, Dr. G. B. Wainwright, for his introduction to Cases I and II.

MASTOID OPERATIONS

A FURTHER SURVEY

BY

WALTER HOWARTH, M.A., M.B., F.R.C.S.

Surgeon to the Ear, Nose, and Throat Department,
St. Thomas's Hospital

AND

GEOFFREY BATEMAN, B.M., F.R.C.S.

Chief Assistant to the Department

In November, 1937, we published in this *Journal* (p. 954) the results of a series of cases operated on for chronic otorrhoea. This series did not include the cases cured by nasal or pharyngeal treatment, but only those requiring mastoid operations. We classified the operations used as Schwartz's, conservative, modified radical, and radical mastoid operations, and gave our definition of these methods. In reviewing these cases we were able to draw certain conclusions and to suggest indications for and contraindications to the various operations. During the past year we have applied these indications to our cases, and it may be of interest to publish the results.

There is such a slight division between acute mastoiditis and early chronic otorrhoea that can be cured by a Schwartz's operation that we will exclude this class of case from our analysis and confine ourselves to cases of well-established chronic otorrhoea. We have operated on eighty ears in seventy-nine patients, the one bilateral case having had two modified radicals. Of these, twelve had conservative mastoid, forty-five had modified radical, and twenty-three had radical mastoid operations.

The Conservative Mastoid Operation

The conservative mastoid operation when successful gives such satisfactory results that one is apt to attempt it even when contraindications are present, and in three of our cases we adopted this method in spite of finding cholesteatomatous material in the antrum. One of these has since been converted into a radical, and another requires re-operation. The third developed a post-auricular abscess, which was drained, and eight months after operation the ear became dry, and has now been dry for a month, but it is doubtful if it will remain so. Including these three cases, of the twelve conservative operations, eight resulted in dry ears, of which two broke down again and one has been re-operated upon; four have never dried up, and one of these has been operated on again.

The six successful cases had central perforations, except one which had a low posterior marginal perforation with granulations growing from the tympanic ring external to the tympanic membrane. This patient has

had a dry ear with good hearing for ten months, and it is the occurrence of a case like this that makes it difficult to choose cases for this operation. The factor which made us think it was worth trying in this instance was the presence of greenish glairy fluid in the mastoid antrum and air cells, and the absence of any cholesteatoma or granulations in the antrum and attic. All the five cases with central perforations had cellular mastoids with glairy fluid in the cells. This seems to be the best indication for a conservative operation, and, as is seen, six of our cases with this condition were successful and three of the five which did not result in dry ears had a similar mastoid condition. These three patients were aged 9, 24, and 25 years, and the only factor common to them was the long duration of the otorrhoea before operation. We thus see that the cases in this year's series bear out the conclusions we came to last year, and the main reason why our figures are not better is that we did not invariably follow our own indications, as the temptation to try the operation in the first instance is very great. If now we examine this series and exclude from it the cases we should have excluded if we had followed our own indications strictly, we find that eight would have had this operation: five of the eight have dry ears, and the other three are well and have only a mucous discharge from the middle ear. Of the remaining four cases, one has a dry ear, two have again been operated on, and the fourth is suffering from giddiness and has been recommended for further operation.

Our indications for the conservative mastoid operation can now be revised and stated. We consider that it should be confined to those cases in which:

1. The chronic otorrhoea cannot be cured by conservative treatment or surgical treatment to the nasopharynx.
2. The perforation is not in the attic, in Shrapnell's membrane, or in the high posterior region.
3. The mastoid is cellular with glairy fluid in the cells.
4. Granulation or cholesteatoma is absent in the antrum or attic.

The Modified Radical

We have performed forty-five modified radical operations during the year. This operation can be briefly described as a classical radical mastoid operation with this modification: that the tympanic membrane and malleus are not removed and the middle ear is therefore not unduly disturbed.

Of the forty-five patients, twenty-one have dry ears; in eighteen the ears remain moist, but are satisfactory in that there is no indication for any further surgery and it seems probable that the majority will become dry in the course of time. No recent information can be obtained from the remaining six cases as they live too far away. In no case is there any indication for further operation.

Of these cases twelve had cholesteatoma in the attic and antrum and fourteen had polypi or granulations in the external auditory meatus; eight had had previous mastoid operations, either Schwartze or conservative; and twelve had high posterior marginal perforations. The cases which do not come into these categories had central perforations and were not suitable for a conservative operation because of the presence of granulations in the antrum or attic. The type of case with the large reniform perforation forms many of those which are moist but satisfactory: it is often difficult to get the middle ear dry after operation.

On the whole we are satisfied with these operations and see no reason to alter the indications given in our previous paper. There is one modification in operative technique which we have adopted with success in four cases. In the past, cases which were otherwise suitable for a modified radical have had a radical mastoid performed because there was a cholesteatoma in the attic that could not be cleared without removing the malleus. In these four cases the head of the malleus was excised, the neck being cut through just above the short process, and the attic was cleared, leaving the tympanic membrane intact.

The indications for a modified radical operation are thus:

1. Cases which need a mastoid operation and are not suitable for a conservative mastoid.
2. Cases in which there is enough tympanic membrane left to make it worth preserving.

The Radical Mastoid

We have performed a radical mastoid operation in twenty-three cases, of which six are dry and sixteen are moist but satisfactory. We expect many of the latter to be dry in the course of time. Of the six that are dry, the average time taken was three and a half months. In all the cases the middle ear was very seriously disorganized, and seven had had previous mastoid operations—three the Schwartze, two the conservative, and two the radical mastoid. It may seem somewhat unsatisfactory that only six of the ears are absolutely dry, but it is not easy to see what alteration in technique would improve the results. The figures are probably misleading, as all these cases have been operated on in the last twelve months, and those described as "almost dry" and "very satisfactory, moist," when last seen soon after operation and some months ago, are not included with the dry ears.

Among these cases there is only one which seems likely to need further operation, and this is a case in which the meatus has become extremely narrowed so that it is difficult to treat the cavity.

Conclusion

In our previous paper we stated that the objects of any mastoid operation were: (1) to make the patient safe with regard to intracranial complications; (2) to preserve the hearing; (3) to cure the suppuration and so produce a dry ear; and (4) to avoid prolonged after-treatment. The conservative operation is the only one to achieve all these objects when successful, but when the ear remains moist it fails to fulfil, in our opinion, the most important essential—that is, make the patient safe. This, we believe, is literally of vital importance, and that is why only twelve patients of the seventy-nine have had this operation. The modified radical operation fulfils object No. 1, sometimes No. 2, often No. 3, and never No. 4. The classical radical fulfils object No. 1, rarely No. 2, occasionally No. 3, and never No. 4.

Thus the method of choice is the conservative operation, in the rare cases where it is not contraindicated; it is applicable to only 10 per cent. of the cases attending the clinic. If that operation is contraindicated, the modified radical operation is performed in about 60 per cent. of cases. The remainder, some 30 per cent., require a radical operation because the complete disorganization of the middle ear contraindicates any other method.

The degree of destruction of the middle ear does not appear to depend on the duration of the infection, for

the average age of the patients in the various groups is, somewhat to our surprise, almost identical: conservative mastoids, 23 years old; modified radicals, 25½ years; radicals, 24 years.

Summary

A survey is given of cases operated on for chronic otorrhoea during the past year.

The results of the various operations are examined.

Indications for the choice of each method are discussed.

ASSOCIATION OF STAMMERING AND THE ALLERGIC DIATHESIS

BY

A. M. KENNEDY, M.D., F.R.C.P.

*Professor of Medicine in the University of Wales and Director
of the Medical Unit, School of Medicine, Cardiff*

AND

D. A. WILLIAMS, B.Sc., M.D.

*Deputy Medical Superintendent, Llandough Hospital, Cardiff;
Late Assistant in the Medical Unit, School of
Medicine, Cardiff*

The mechanism of speech is a complicated process in which the diaphragm, the muscles controlling the vocal cords, and those of articulation, as in the palate, tongue, and lips (with the teeth), are mainly concerned. Further, these structures are under the control of the central nervous system, and ideas therein originated are given expression in speech through association fibres, the speech centres, and the centres controlling these peripheral muscles. The uninterrupted flow of speech depends upon the proper functioning and co-ordination of all these structures, central and peripheral. Stammering does not depend upon any gross anatomical defect, but is due, apparently, to some disturbance of this essential co-ordination between the various factors responsible for the production of speech. But what is the underlying cause of this disturbance?

Although usually described as a disorder of speech, stammering is really something more, and certain traits of character may be observed in the stammering child. He is often "nervous" and excitable—sometimes with a tendency to suppressed anxiety—and this mental tension often produces physical tension. A general tendency to excitability and nervousness has been noted in family histories and also a tendency for stammering to run in families, but, notwithstanding a rather unstable and nervous temperament, the stammerer is usually intelligent and has a good brain.

One morning, some months ago, three asthmatics happened to present themselves at this medical unit for interview, one shortly after the other. There would have been nothing remarkable in this but for the extraordinary coincidence that each proved to be a stammerer. The thought immediately occurred to one of us (A. M. K.) of the possible association of stammering with asthma and, having regard to the allergic aetiology of the latter, other allergic manifestations. Recalling some resemblance in certain features of allergic individuals and stammerers, it appeared that an inquiry into the presence or absence of allergic manifestations in the personal history of the stammerer and his family might yield results of some note. Accordingly arrangements were made to examine a con-

secutive series of 100 children who suffered from stammer.

Through the kind offices of Dr. Greenwood Wilson and Dr. Colston Williams (medical officers of health and school medical officers) of the city of Cardiff and county of Glamorgan respectively, we were enabled to examine 100 school children selected by head teachers because they were stammerers. These were children, 5 to 14 years of age, who were attending elementary schools in Cardiff and the neighbouring towns of Penarth, Caerphilly, and Bargoed, and were representative of town, suburban, and industrial areas. The parents or guardians were invited to bring them for special examination. Some children, however, came unaccompanied and, as it was thus impossible to obtain any family or other history, they were discarded. Likewise two adopted children, whose foster parents knew nothing of their family history, were also discarded. Again, in certain cases the speech defect proved to be dependent upon some anatomical fault, such as cleft-palate or hare-lip, and in others the children were mentally retarded and the power of speech was immature. Some exhibited nasal speech or were mere "lispers." None of these was a stammerer, and so all were excluded from the investigation. No other selection was made, and the remainder were examined in rotation until 100 true stammerers had been seen.

Each child was examined personally and the parent or guardian cross-questioned. Careful inquiry was made for any personal or family history of allergy or allergic inheritance, and questions were asked in regard to such allergic manifestations as asthma, eczema, hay-fever, migraine, and urticaria. Caution was often necessary in framing the questions relative to family history, for some parents were inclined to boast that theirs "was always a healthy family" or that "there never was any trouble or disease in our family." Some seemed to think that questions, particularly in regard to skin eruptions—eczema and urticaria—cast rather a reflection on them, whereas most quite freely admitted if there was any incidence of asthma in the family. With tact and patience, however, the family history usually came out clearly and the parent became quite interested. With regard to migraine we accepted as evidence headaches, periodically recurring and severe, principally unilateral or over the temple and throbbing in character, often accompanied by visual disturbances and vomiting, and all against a background of good health.

It was not unusual in such cases to get a history of stomach trouble, sickness, vomiting, or "bilious attacks," without any mention of associated headaches until direct questions were asked. Apart from the question of migraine note was taken of any aversion to or gastro-intestinal upsets following particular foods, or "fastidiousness" regarding food generally, exhibited by the child and suggestive of food allergy. The family history on both paternal and maternal sides was carefully sifted, and at the same time the opportunity was taken of noting whether there was any family history of stammering and whether the child was right- or left-handed.

Of the 100 children examined eighty-one were boys and nineteen girls; eighty-nine proved to be right-handed and eleven left-handed; and a family history of stammer was present in sixty-five cases and absent in thirty-five.

Incidence and Nature of Allergy Present

1.—CHILDREN WITH A PERSONAL HISTORY OF ALLERGY (52 CASES)

(a) Fifty-two children gave a personal history of allergic manifestations, as shown in the following table:

Discussion

While hypersensitiveness in the human subject may occasionally be acquired, the importance of the hereditary factor in allergic conditions is now generally accepted. In a few cases the particular type of allergy appears to be inherited; more often, however, specific sensitivity is not inherited, but the tendency to become sensitive is transmitted from one generation to another. It is not necessarily the disease, such as asthma or urticaria, which is inherited, but the constitutional make-up or allergic diathesis which predisposes descendants to the development of sensitiveness. They do not of necessity suffer from the same type of allergic manifestation as their forebears, but they may become sensitive to any allergic agent with which they come into adequate contact at any time from birth onwards. The allergic individual is one who is constitutionally susceptible.

The predisposition is localized, as a rule, in some particular group of cells in special tissues or organs of the body, but an allergic reaction does not occur until the specific allergen to which the patient is sensitive comes into adequate contact with them. The variability of the allergic symptoms is due to the fact that the location of the groups of potentially sensitive cells is not constant.

Vasomotor reactions in the tissues, transitory and reversible, are the principal local features of the allergic response in the human being—first vascular spasm, then capillary dilatation and increased permeability resulting in an exudation of oedematous fluid and cellular infiltration, chiefly eosinophils—and so it has been suggested that allergic individuals inherit an unstable vasomotor system. But vasomotor irritability—seen particularly in urticaria and angioneurotic oedema—is probably part of the constitutional “make-up” of allergic subjects, and is an accompaniment, but not the primary cause, of the allergic state. Vasomotor instability occurs in other conditions, but when it is present in individuals with the allergic diathesis or inherited predisposition to become sensitive to allergens it probably plays some part in the production of symptoms.

As previously noted, a general tendency to excitability and nervousness often runs in the families of stammerers. The stammerer himself is apt to be “nervous” and excitable, and his mental tension—suppressed anxiety—often causes physical tension. Fear, anxiety, and other emotions generally cause an aggravation of his stammer. Nervous, emotional, or psychical stimuli have also considerable influence in allergic conditions; and in asthma, for example, it has been suggested that psychological factors, such as fear, anxiety, anger, and similar emotions, may precipitate an attack. It would appear, however, that such agents are of little importance in the absence of the allergic predisposition, but in individuals already so predisposed emotional disturbances may act as aggravating factors and possibly precipitate a reaction.

Nervous and emotional disturbances are not the cause of the allergic state, but may accompany or result from it, and consequently allergic individuals may be specially alert and active mentally. Stammerers also, it may be recalled, are usually intelligent and have good brains, notwithstanding their rather unstable and nervous temperaments. The close connexion of the nervous and vascular systems (Forbes and Cobb, 1938) provides the path through which the latter may be influenced by fear, anxiety, anger, and other emotional and nervous disturbances.

In allergic migraine the hereditary factor is particularly strong, and the exciting factor is usually a food allergen. Here it may be recalled that sixty-five of the 100 stammering children investigated gave a *family* history of migraine and thirty-two a *personal* history of it. Incidentally, forty-five had a *personal* history of “fastidiousness” in regard to food generally, refusals or dislikes of, or upsets after, certain foods. The particular type of cerebral disturbance responsible for the headaches and other manifestations is thought to be a local allergic reaction producing temporary oedema of the meninges, cortex, or other parts of the brain, with, possibly, vascular spasm. Goltman's (1936) study of a typical case of allergic migraine in which he had the opportunity of making direct observations through an opening in the skull strongly supports this view. Such a mechanism could explain the various transient phenomena of typical migraine, such as visual disturbances, giddiness, paraesthesias, disturbances of speech, twitchings, and local paresis. The sickness and vomiting might also have a similar central origin. The transient disturbance of speech, at times amounting almost to aphasia, which is occasionally an accompaniment of the migrainous seizure, is of special significance in view of the findings in the present investigation into stammering. The observations of Foster Kennedy (1926) on focal cerebral oedema as a cause of cerebral symptoms in angioneurotic oedema also lend support to this view. Reference to the figures given above show that a *personal* history of urticarial attacks was obtained in twenty of the 100 stammering children investigated. In fact, either migraine or urticaria, alone or in combination, and with or without some other allergic manifestation, was present in the *family* histories of seventy children and in the *personal* histories of forty-three.

In view of the close and practically constant association of stammering and allergic manifestations in the personal and family histories of the stammerer; as revealed by the present investigation, it is difficult not to conclude that there is something more in it than a mere casual relationship between stammering and the allergic diathesis. It is not suggested that stammering is the direct result of an allergic reaction; but, considering the high incidence of allergic manifestations in our series of stammerers and accepting the view that the local tissue response in allergy is a vascular one—spasm followed by capillary dilatation and oedematous exudation, transitory and reversible—we may assume the existence of a cerebral cortex which is hypersensitive to any transient vasomotor disturbance brought about not by a specific allergen but by the effort of speech. In any case the findings are suggestive that an attempt to influence the sensitive constitution of the stammerer might at least be worth a trial. The frequency of migraine and “fastidiousness” in regard to food generally which we encountered, and the fact that a food allergen is usually the exciting factor in migraine, suggest that a beginning might be made with special allergic or elimination diets. Even ephedrine might have a place in treatment. But all this is a matter for further study.

Summary and Conclusions

A consecutive series of 100 children who suffered from stammer was examined with a view to discovering the association, if any, between stammering and the allergic diathesis. The personal and family histories of each child were carefully sifted for any evidence of allergic manifestations.

In all cases, except one, positive evidence of allergy was found in the personal or family history. Fifty-two

gave a positive personal history, and forty-eight of these also had a positive family history. Forty-eight gave no personal history, but a positive family history was obtained in all of them except one.

The various allergic manifestations in the personal and family histories have been tabulated and the closeness of the allergic inheritance noted.

A family history of stammer was obtained in sixty-five of the 100 cases, and the closeness of the stammering inheritance has been noted.

Stammering tends to run in families. The hereditary factor plays an important part also in the allergic diathesis—the constitutional "make-up" which is apt to become sensitive being transmitted from one generation to another. A general tendency to excitability and nervousness frequently runs in the families of stammerers, who themselves are often "nervous" and excitable and whose mental tension—suppressed anxiety—often causes physical tension; such emotions generally aggravate the stammer. Nervous, emotional, and psychical stimuli have also an influence in allergic conditions, and it has been suggested that, in asthma, certain emotions—fear, anxiety, etc.—may precipitate an attack. These, however, appear to be mere aggravating factors, and are of importance only in the presence of the allergic predisposition of which they are a frequent accompaniment or a result. The vascular system through its close connexion with the nervous system may be influenced by fear, anxiety, anger, and other emotions, in stammer and also in allergy.

Notwithstanding their nervous and rather unstable temperament, stammerers are usually intelligent and have good brains. Allergic individuals also—for example, sufferers from migraine—are often very alert and active mentally.

In allergic migraine the hereditary factor is particularly strong and the exciting factor usually a food allergen. Sixty-five of the 100 stammering children gave a family history of migraine and thirty-two a personal history of it. Forty-five had a personal history of "fastidiousness" towards food generally or upsets after particular foods.

The close and practically constant association of stammering and allergic manifestations in the personal and family histories of the stammerer, as revealed by the present investigation, rather favours the view that there is something more than a mere casual relationship between stammering and the allergic diathesis.

Kennedy, F. (1926). *Arch. Neurol. Psychiat.*, Chicago, 15, 28.

R. Cento (*Minerva med.*, 1938, 29, 235) records his observations on ten patients with ulcerative tuberculous lesions and purulent sputum containing a large number of bacilli who were treated for thirty consecutive days by intravenous injections of 2 c.cm. of beeswax dissolved in 5 per cent. of olive oil and 10 per cent. of cod-liver oil, combined with calcium by mouth or intravenously. In all the patients after the first ten injections there was a diminution in the quantity of sputum, which subsequently became less purulent; finally there was only a little morning expectoration. In all the ten cases after the first ten to fifteen injections there was a diminution in the number of tubercle bacilli, which assumed a granular appearance and became no longer acid-fast. At the end of treatment four patients became sputum-negative, and in two others it was possible to find only a few acid-fast bacillary forms on examination of the gastric juice. Inoculation of numerous specimens of this sputum on Petraghani tubes produced a macroscopic growth in only two cases.

THREE CASES OF INTUSSUSCEPTION IN THE ADULT

WITH REFERENCE TO AETIOLOGY

BY

C. L. HEANLEY, F.R.C.S., M.R.C.P.

Surgical First Assistant and Surgical Registrar, London Hospital

Acute intussusception in the adult is rare, and then usually occurs in connexion with "tumours" of the intestinal wall (Fiske, 1937; Goodall, 1910); but this is not an essential factor (Bryan, 1937), for in Case III, so far as could be found, no initial cause was present. Several cases have been reported in which the causal tumour was discovered only at subsequent operations (Oughterson and Cheever, 1929). In infants so-called primary intussusception is said to arise in connexion with inflammatory changes in the lymphoid tissue in the mucosa of the lower end of the small intestine (Perrin and Lindsay, 1921). This lymphoid tissue swells, and forms as it were a "tumour." The accompanying illustration shows this

Specimen taken from a fatal case of intussusception in an infant. The caecum and lower few inches of ileum have been opened from behind, and a sessile tumour-like mass of lymphoid tissue is seen about three inches from the ileo-caecal valve. This formed the apex of the intussusception.

"tumour" formation very well. At operation in infants almost invariably the lymph glands in the mesentery are also enlarged, a change not found in these three cases. That so-called primary intussusception does not occur so commonly in the adult is said to be due to the fact that lymphoid tissue becomes reduced with age, as is well seen in the pharyngeal and palatine tonsil areas, and also because the lumen of the intestine is relatively larger in the adult.

Intussusception differs from other forms of intestinal obstruction in the fact that the patient usually passes stool, as is well shown here. In infants the stool often contains blood and mucus, but in these cases no blood was noticed.

Case I

In December, 1937, a woman aged 47 was admitted to hospital complaining of ten days' intermittent abdominal pain. Her history contained nothing of note save an attack of abdominal colic one year previously that lasted a few hours only.

Ten days before admission there was an onset of mild generalized abdominal pain not associated with vomiting. Seven days before admission the pains became more severe, and were

associated with vomiting. She volunteered the statement that they were like labour pains, lasting two minutes every ten minutes. The pain was localized to an area to the right of the umbilicus, and persisted most of the day. Five days before admission she was almost free from pain, but as her bowels had not been opened since the onset of the pains she took senna. Four days before admission her bowels were open, but the pains became more severe and she vomited many times. Two days before admission she again took senna, with the same result: the pains became very severe and there was much vomiting. On the day of admission her bowels were open. (On no occasion did she pass blood.) The pains and the vomiting continued.

Examination.—Her temperature was 98° and pulse 80. She was seen to have a typical attack of abdominal colic. On inspection a mass was observed in the abdomen, to the right of and below the umbilicus; it was dull to percussion, and was tender but not fixed. Her private doctor had pointed out that the mass became harder during an attack of colic. On rectal examination no abnormality was found, and no blood. In spite of the low pulse and temperature, a diagnosis was made of appendix abscess, with involvement of gut causing intestinal obstruction.

Operation (by C. L. H., under general anaesthesia).—An intussusception was present, the apex of which was in the transverse colon. On reduction it was found that a sessile tumour, 2 cm. in diameter, situated in the small intestine three inches above the ileo-caecal valve, had formed the apex of the intussusception. Reduction of the intussusception was easy up to the ileo-caecal valve; the last part—that is, reduction of the tumour and the ileum out of the colon—gave some difficulty. To remove the tumour it was necessary to open the gut, which was closed in two layers. No other tumours were found in the limited part of ileum examined.

When seen in May, 1938, the woman was very well.

I am indebted to Dr. Gilmour of the Bernhard Baron Institute of Pathology of the London Hospital for the following report and observations on the tumour.

PATHOLOGICAL REPORT

The specimen was a nodule 2 cm. in diameter received in 4 per cent. formaldehyde. The greater part was round, smooth, and brown, but one surface, 1.5 cm. in diameter—the cut surface of removal—was flat and showed rough white muscularis. On section the round part showed an outer zone, up to 1.5 mm. deep, of firm brownish or yellowish-white thickened mucosa which was ill defined inferiorly. Beneath this was a firm yellowish-white mass in the submucosa which infiltrated the muscularis. The muscularis was hypertrophied up to 4 mm. thick.

Microscopically the growth shows polygonal and columnar cells arranged in branching and anastomosing trabeculae, many of which contain alveolar spaces. The trabeculae are often two cells wide, but many are much wider. The cells at the borders of the trabeculae and surrounding alveolar spaces are palisaded and usually columnar. The remaining cells are polygonal. The cytoplasm in the basal parts of the columnar cells and in the smaller polygonal cells is dense, but in the larger polygonal cells is slightly rarefied. The denser cells are stained deep red or purple, and appear indistinctly granular in haematoxylin and eosin. The granularity is most marked in the bases of the columnar cells. The less dense cells are deeply stained and show distinct pink or purple granules. A few cells contain small vacuoles. In some places where the cells are separated slightly they are seen to be connected by intercellular protoplasmic bridges not unlike the prickles of squamous epithelium. By Fontan's silver impregnation the basal cytoplasm of the columnar cells, and to a much less extent the cytoplasm of other cells, shows numerous finely particulate argentaffin granules. The borders of the trabeculae are consequently outlined sharply by this method. Sections of tissue fixed for six weeks in formaldehyde, transferred to Müller's fluid for one week and embedded in paraffin, showed the chromaffin reaction. The chromaffin reaction was also obtained by placing for four days in Müller's fluid paraffin

sections of formalin-fixed tissue. The reaction is seen as a bright lemon-yellow diffuse coloration of the parts of the cells that show abundant argentaffin granules. The chromaffin reaction differs from that given by the adrenal medulla in its colour and by the fact that it is given by tissue fixed in formaldehyde for a considerable time. Other argentaffinomas examined by me have shown these peculiarities in the chromaffin reaction. Only a very few cells contain a scanty amount of cholesterol esters yielding liquid crystals on heating. The nuclei are uniform, small, and round, with prominent nuclear membranes, pale nucleoplasm, a scanty net of delicate chromatin threads, several small nodes, and one to three small nucleoli. The alveolar spaces are small, and contain a lightly stained vacuolated coagulum. The stroma of the growth is scanty, and consists of collagenous and smooth muscle fibres and a few vessels. Some of its spindle cells contain a little granular fat.

The mucosa has lost its superficial epithelium, is inflamed, and is extensively infiltrated by growth; intestinal tubules are very scanty. The muscularis mucosae is slightly thickened and gives extensions into the stroma of the growth beneath. The small amount of muscularis present in the section is infiltrated by trabeculae of the growth.

The tumour is an argentaffinoma, locally malignant in that it is growing by infiltration.

Case II

In March, 1936, a woman aged 66 came to hospital complaining of severe abdominal pain. She had been admitted on two previous occasions on account of attacks of abdominal colic, but on investigation no cause was found.

On the day before admission she had severe colicky abdominal pain, most marked to the right of the umbilicus, but radiating to the left side and to the back, though not to the shoulders. The pain was associated with much vomiting and diarrhoea: no blood was seen in the stools.

Examination.—Her temperature was 99° and pulse 120. The notes state that examination of the abdomen revealed rigidity of an area to the right of the umbilicus, deep to which there was a rounded tumour "which suddenly disappears." No abnormality was found on rectal examination. A diagnosis of intestinal obstruction due to a gall-stone was made in view of the previous history of colic.

Operation (by Mr. Alan Perry, under spinal anaesthesia).—An intussusception, ileo-ileal, was present, which was about two feet in length from point of entry to apex. Reduction was not difficult, and at the apex was found a sessile tumour (a lipoma) 3 by 1.5 cm. in diameter. To remove the tumour it was necessary to open the gut, which was closed in two layers. The gall-bladder contained one large stone about an inch in diameter. Convalescence was satisfactory.

The pathological report stated that there was venous engorgement and acute inflammation of a subserous intramuscular lipoma of the ileum, with ulceration of overlying mucosa.

The patient was well when seen in January, 1938. She complained of flatulence, but had had no other attacks of colic since the operation.

Case III

In May, 1935, a man aged 27 was admitted to hospital complaining of eight hours' abdominal pain. He had had an attack four and a half years previously. Pain started in the region of the umbilicus, and later shifted to the right iliac fossa. Since then, every one or two months, he has had at night attacks of abdominal pain which lasted a few hours. The pain usually remained in the region of the umbilicus.

Eight hours before admission he had severe colicky abdominal pain which made him "double up." The pain was associated with vomiting. The bowels had been open once since the onset of the pain.

Examination.—The temperature was 98.8° and pulse 78. The abdomen was tender and rigid on the right side, but no abnormal lumps were felt. Rectal examination revealed

nothing abnormal. A diagnosis of acute appendicitis was made.

Operation (by Mr. Hirschfeld, under general anaesthesia).—An intussusception was present. The apex of the intussusception was in the transverse colon, and on reduction it was found to be the ileo-caecal valve. No tumour or other cause was discovered. The appendix was removed. Convalescence was satisfactory.

The pathological report stated that there was venous engorgement of the appendix.

One month after operation the patient was well, having had no more attacks of pain since. He has answered subsequent inquiries, and wrote in March, 1938, that he had been very well.

Summary

The rarity of cases of acute intussusception in the adult, and the aetiology of the condition, are discussed.

The history of three recent cases is given. In two of these the causative factor was a neoplasm.

I am indebted to Mr. H. S. Souttar and Mr. Alan Perry for permission to publish the notes of the three cases, which were under their care in the London Hospital.

CONGENITAL DEFORMITIES OF LEGS

BY

REGINALD BROOMHEAD, M.B., Ch.B., F.R.C.S.

Honorary Surgeon, Orthopaedic Department, General Infirmary, Leeds; Lecturer in Orthopaedics, University of Leeds

On December 1, 1936, a girl aged 16 was brought to me as she was said to have been "horn without any legs." She came into my consulting-room walking on her hands, using the base of her trunk as a middle support. She was a most curious sight when I first saw her: one had the impression of a rather large dog coming into the room, an impression made stronger when she leaped from the floor to an ordinary chair and squatted on her haunches with a rather pleased smile at her trick. Her speed when "walking" was amazing; she could cross the room as fast as an ordinary adult, and when she wished to sit on a chair she leaped into it and sat like an ordinary human being. The change from the ambulatory position on the floor, where she looked like a domestic animal, to that on a chair, where she took on the appearance of an ordinary individual, was dramatic. She stood with most of her weight on her left lower limb, and the two curious teat-like projections from the right lower limb enabled her to balance herself on her two "legs" with the aid of one hand. She wore a large sock to cover the right stump, and a boot—much deformed—on the left foot.

On examining her more closely one found that through constantly walking on the palms of her hands with the wrists dorsiflexed she had developed a greatly thickened palmar skin, comparable in character to that of the sole of the foot and studded with "hoofs." Apart from the acquired thickening of the palmar skin and the congenital deformities of the legs the girl was normal. The "legs" themselves were very interesting, and are well shown in Fig. 1. The right one was about 6 inches long, as

measured from the great trochanter; it was a large fat stump ending in two teat-like projections, presumably abortive toes, and looked for all the world like a cow's udder. One could feel bones inside the left "leg," which was about a foot long, and had a femur, a tibia, and three inner toes; the fibula and two outer toes were missing, and the dimple over the tibia so characteristic of the con-

FIG. 1.

genitally absent fibula was present. X-ray photographs revealed that both hips were dislocated, and that there was an abortive femur with condyles in the right stump and an immature femur and tibia in the left stump.

The girl herself, content for many years, was now reaching womanhood, and wanted to be the same height as others and to walk like others. Was it possible? My first thought was to straighten the left knee and to put the left foot into full equinus in order to make the left lower limb as long as possible. Afterwards the limb would have been fitted into the socket of an artificial limb which had a knee-joint at the usual level. I have done this before in a similar unilateral case with success. I thought we might fit a tilting-table leg to the right stump. Her bodily development was good, and there was no doubt she would be able to use a tilting-table leg satisfactorily.

Those responsible for the girl were not in favour of an amputation of the right stump, as they were afraid that, if the attempt to make the girl walk failed, the operation might have ruined any return to her original method of progression. I wished for a further opinion, and sent her to my friend the late Dr. H. R. Moxon, at Queen Mary's Hospital, Roehampton, making use of the Ministry of Pensions scheme whereby civilians have the advantage of advice from expert military limb-fitting surgeons.

Dr. Moxon's Report on the Case

"The fitting of artificial limbs in this case, though presenting difficulties common to all such cases of deformity, nevertheless does not present insuperable difficulties—in fact, I think there is a reasonable chance of obtaining quite a successful result. This is enhanced by one very important asset—namely, the girl's obvious wish to be fitted and look like a normal girl in height and appearance, by which her willing co-operation is assured. Also youth and strength are on her side, and thus the physical and mental aspects are favourable.

"*Right Side.*—This should be fitted with a metal tilting-table leg made as light as possible, with the body weight taken accurately on the tuber ischii. The stump, however, is at present much too long, measuring about 6 inches. Shortening by at least 3 inches is necessary, the aim being to give a snugly fitting socket without too much prominence in front, which would be unsightly under the skirt and would at the same time make balancing more difficult and get in the way of the instrument on the left side.

"*Left Side.*—Operation is not recommended. It is suggested that an apparatus should be fitted by which her body weight is taken on the tuber and the foot is supported on a platform partly enclosed in an artificial knee with an artificial shin and foot below. Then it seems fairly certain that by means of a double knee-cap and various straps the knee and foot can be gradually pulled into position. This result would improve as time went on, and need not be a painful process in any way in a properly adjusted instrument.

"This being the general outline of the case, the stages recommended are as follows:

"1. Shortening of the Right Stump.—When this is ready for fitting, which should not be before three months from the date of operation, she should be sent as an in-patient to Roehampton, prepared to stay at least two months. This is very necessary, as she has never walked and has to be taught to do so and get her balance, etc., just like an infant. Regarding her present method of locomotion, this would not be interfered with by shortening the stump if she fails to manage with artificial limbs, as she would still have the buttock; and it is noted that when she gets about on the floor she takes the weight on the left leg and hands chiefly.

"2. On admission a start would be made with the left side in order to get the necessary height, the height of the tilting table being gauged therefrom and increased by graduated blocks. It will be noted that, in view of the double dislocation, the weight on each side will be taken on the tuber ischii and not on the axillae.

"In conclusion, I think that there is a very good chance of success in this case, difficult as it is, and that the girl will be able to walk in comfort with fairly normal gait.

"X-ray appearance (copied from x-ray report submitted).—The pelvis: Well developed, but of the android type. Hips: Congenital dislocation on both sides, and on the right side the head of the femur is separate from the shaft. The legs: On the right side the femur is very imperfectly developed, with a very short and thin diaphysis and the head developed separately from it; the parts below the knee-joint are all very rudimentary. The left shows a fairly well developed femur and tibia, but absent fibula."

I was rather surprised to see that Dr. Moxon suggested gradual straightening of the left limb. I felt that as the girl was to have an operation it would be better to straighten the left leg operatively, as it would be quicker and less tiresome for the patient. However, after discussing the matter we decided to do as the limb-fitting surgeon suggested. The limb-fitting was Dr. Moxon's work, and his arguments were as follows:

"It is not the intention to fit the girl's left leg into the socket of an ordinary artificial limb, as this could not be recommended as a practical procedure. Therefore, the preliminary straightening of the left leg for that purpose does not arise.

"The type of apparatus recommended for the left leg is in reality a combination of surgical instrument above, with the knee, shin, and foot of an artificial limb below. The principle of such an apparatus is illustrated on page 58 of 'Solvitur Ambulando,' but each individual set-up must differ in detail according to the requirements of the particular case of deformity under consideration. In this case it is felt that an instrument on this principle can be fitted to the girl's left leg with reasonable prospect of success without any preliminary straightening operation, open or otherwise. Preservation of her present mode of progression is in my opinion of prime importance.

"When not wearing the legs, or if the fitting of them should unfortunately be unsuccessful, she can still get about as before, which she certainly would not be able to do again if the left leg were previously straightened by operation."

Accordingly, on June 15, 1937, I removed about four inches of femur from the right stump together with a large amount of skin and subcutaneous fat and the two teats,

using a posterior flap. The resulting stump was very satisfactory, being a much better shape and size for the fitting of a tilting-table leg (Fig. 2).

After three or four months she went to Roehampton, where she remained an in-patient for five months. The following is taken from a letter I received from Messrs. Hanger and Co., who supplied the patient's artificial legs:

"When Miss R. came to us, apart from a wheeled chair her only means of locomotion for seventeen years had been on her hands and haunches. It was found that the moment she was placed in an erect position on any form of temporary pro-

FIG. 2.

FIG. 3.

thesis, even a few inches from the ground, a sense of balance was entirely lacking and she became giddy. We gradually accustomed her to being off the ground at progressively increased heights, until eventually she was able to retain her balance when raised to her normal height of 5 ft. 1 in.

"For the deformity on the right side we provided her with a prosthesis of the normal type for an amputation involving disarticulation of the hip-joint, similar to that illustrated on pages 49 and 50 of our brochure 'Solvitur Ambulando.'

"For the left leg—a special appliance was devised, comprising a thigh socket and surgical boot rigidly mounted to a ball-bearing knee-joint (embodying an automatic knee-lock) connected to a light metal shin-piece with an articulated foot and toe-piece.

"In designing these prostheses light weight combined with ample strength and practical efficiency were the essentials required for a successful result. It was found, however, that when she was first fitted she had not the slightest idea of how to walk; but she proved a very apt pupil, and in a short time had learnt the movements required.

"From this time she made rapid progress, and when she left our hands was walking distances of half a mile with perfect confidence and without undue fatigue, using two walking-sticks. She can walk with one stick, but at present it is inadvisable that she should do so. We think, however, that when she has become quite accustomed to these prostheses she will find only one stick necessary."

When I saw the girl in May, 1938, she was able to walk quite well on the level with the aid of one stick. She climbed by herself up a short staircase with complete self-assurance. Fig. 3 shows the girl and her new legs. When fully dressed she is to all intents and purposes an ordinary individual. Her whole outlook is changed, and

she is now a self-reliant girl with a place in life instead of being a circus curiosity.

She has an electric chair for taking her from one building to another, but, having arrived, she can now walk like other people and take a normal part in the work of the day. In her own words she says (July 5, 1938): "I can nearly do everything now, and do not ache so."

Since sending this article for publication I have heard (November, 1938) from the girl's doctor that she is now progressing with increasing freedom and is beginning to learn to dance.

I am very grateful to many who have helped me to bring about this result: my own staff, that of the Ministry of Pensions, Messrs. Hanger and Co. (the artificial-limb makers), and one whom I mention by name, the late Dr. H. R. (George) Moxon, who unfortunately did not live to see such a happy result of his advice.

Clinical Memoranda

Carcinogenicity of the Tar-Creosote Mixture used by Fishermen

This tar-creosote mixture was submitted for investigation by Dr. C. C. McKenzie of Campbelltown, who suspected it of being responsible for cases of cancer of the lip in the local fishermen. The carcinogenicity of the mixture was tested by painting the skin of thirty stock mice, in the interscapular region, three times a week. After the second application epilation of the whole painted area occurred. A severe dermatitis, resulting in ulceration, followed, the ulcers penetrating so deeply that scars were produced.

Twenty-one mice survived for longer than three months. The first papilloma occurred after 106 days. In his pathological report Dr. L. Woodhouse Price stated: "This is a keratinizing squamous epithelial papilloma, showing very early malignant change." Eleven papillomata developed in these mice from the 106th to the 249th day. By this time all mice had either died or had to be killed because of the extensive ulceration. The papillomata developed on the edges of the ulcerations, except in one case, in which the papilloma occurred within the ulcerated area. In the sections of the more recently examined tumours cell-nest formation and a good deal of deep infiltration are to be seen. Their histology is that of well-differentiated squamous carcinoma; however, the panniculus carnosus does not appear to be infiltrated with the tumour, which therefore is termed a papilloma malignum. In mouse No. 599 the lung showed macroscopically a definite tumour, and histologically the structure of anaplastic new growth, probably a lung adenoma, 197 days after the start of painting. It is known that the application of tar to the skin of mice increases the number of lung adenomata, as compared with controls.

There is no doubt that this tar-creosote mixture, which comes in contact with the lips of the fishermen, is carcinogenic. This source of occupational cancer can and should be eliminated. It is necessary either to produce a suitable non-carcinogenic tar, possibly by distillation at lower temperature than at present, or to educate the fishermen to abandon the habit of putting the bone or wooden needle, threaded with tarred twine, between their lips while mending their nets.

Royal Cancer Hospital.

Reviews

GUIDANCE IN OBSTETRICS

Midwifery. By Ten Teachers. Under the direction of Clifford White, M.D., B.S., F.R.C.P., F.R.C.S., F.C.O.G. Edited by Sir Comyns Berkeley, Clifford White, and Frank Cook. Sixth edition. (Pp. 676; 262 figures, 9 plates. 18s. net.) London: Edward Arnold and Co. 1938.

The new edition of this textbook follows closely on the reprinted fifth edition published last year. Since then there have been extensive changes in the personnel of the "Ten Teachers" and minor changes in the book. The editor has reduced its size by discarding obsolete material contained in the previous edition. Further improvement is possible when two pages are devoted to each of such rarities as locked twins and pseudocyesis, and several pages contain an unconvincing attempt to differentiate between albuminuria of pregnancy and pre-eclampsia.

The illustrations throughout are excellent, and include four colour plates and five radiographs. One of these must be criticized for suggesting that dilatation of the renal tract is evidence of pyelitis of pregnancy. Students should have little difficulty in remembering the positions in face presentation, since the illustrations on page 304 rather suggest a Dictator extricating himself from a difficult situation. Those with more "left" tendencies will find solace in the clenched fist on page 327.

Cervical polypi are not included as a cause of bleeding in pregnancy; transfusion is not mentioned in treatment of severe cases of obstetrical shock, melaena neonatorum, or familial jaundice; nor is vomiting included in the list of danger signs during the later ante-natal period. The dosage of ergometrine advised for post-partum haemorrhage is small and its action is incorrectly stated to be slow. Many obstetricians will disagree with the statement that it is quite unnecessary to displace the foetal head during manual rotation from a posterior position. Omission of the preliminary step of disimpaction is a frequent cause of failure to accomplish the operation, and is the indirect cause of many difficult and dangerous face-to-pubis extractions. Conservative opinion will regret that a breech with extended legs in a primigravida—even in twin pregnancy—is now a "rational indication" for Caesarean section, and that this rule should not be broken unless the infant is premature. So much by way of criticism.

This book is a well-established favourite with students, and the new edition is certain to be as popular as its predecessors and perhaps even more helpful.

MODERN SURGERY

The Essentials of Modern Surgery. Edited by R. M. Handfield-Jones, M.S., F.R.C.S., and A. E. Porritt, M.A., M.Ch., F.R.C.S. (Pp. 1,126; illustrated. 30s.; postage 10d., abroad 2s. 3d.) Edinburgh: E. and S. Livingstone. 1938.

This is a single volume, the composite work of fifteen authors, six of whom, including the two editors, are on the staff of St. Mary's Hospital, while with one exception (Mr. Walter Mercer of Edinburgh, who writes on deformities) the others are also London surgeons. Its scope is comprehensive: chapters on physiotherapy and radiotherapy, venereal diseases, diseases of the skin, diseases of the female genital organs, the ear, and the affections of the nose and accessory sinuses are included in addition to those on general surgery, which for the most part is dealt with on a regional basis. The format is attractive, the text clear, and the print large and easily

readable, while the illustrations, which include photographs of patients, apparatus, and pathological specimens as well as x-ray prints and line diagrams, are interspersed with the text and the whole is produced on art paper.

The editors tell us in their preface that their object has been to provide students and practitioners with the essentials of modern surgery in as concise a form as possible, and also to produce a book which will be of use to students studying for higher examinations. In large measure they may be said to have achieved these objects, though in common with all works of multiple authorship this book necessarily lacks the consistent style of the text of a single author or of those famous old dual authorship works such as Rose and Carless and Thomson and Miles. While certain sections are models of what concise accounts should be for a student, the same cannot be said of all. It is rather disappointing to find included in such a limited work illustrations and accounts of surgical curiosities or rarities, since the student tends to gain a wrong perspective therefrom and to regard these as of everyday occurrence: as examples may be cited a picture of an enormous adventitious bursa over the left shoulder, while photographs of a dislocated shoulder or of a lipoma in this region are missing. The statement (p. 324) in reference to thyrotoxicosis that "in every case a routine examination will search for focal sepsis and appropriate treatment be directed to any such lesion" might be qualified, since patients have succumbed to tonsillectomy performed in this condition instead of an attack being made on the thyroid in the first instance.

We regard the chapters on the ear and on the brain and its coverings as some of the best in the book, and the latter section is particularly well illustrated. The inclusion of prescriptions such as those which appear on pages 200 and 201 is pleasing, and past and present students of St. Mary's will be interested in Fig. 68 (p. 206) and its legend, which reads: "Rhynchophyma. A man known to many generations of students of St. Mary's Hospital." Considered as a whole this book has much to recommend it, and it should take its place as one of the students' standard textbooks of surgery.

HAEMORRHOIDS AND THEIR TREATMENT

Haemorrhoids. By Marion C. Pruitt, M.D., F.R.C.S.Ed., F.A.C.S. (Pp. 170; 73 figures, including 7 in colour. 18s. net.) London: Henry Kimpton. 1938.

Dr. Pruitt has succeeded in writing a simple and clear treatise on the subject of haemorrhoids. A good classification of types of haemorrhoids is given, and it is rightly pointed out that as there are several types no one method of treatment is suitable for them all. Spinal anaesthesia used as routine for operative treatment is thought undesirable and local anaesthesia is favoured. It is surprising to note that oedema is considered the reason for irreducibility of a haemorrhoid and that suturing of the subcutaneous tissues may be carried out after excision of an external haemorrhoid. The author recommends urgent haemorrhoidectomy for uncomplicated irreducible internal haemorrhoids when there is a risk of strangulation, etc.; but this must be quite unnecessary when simple and effective methods are available. The chapter on injection treatment pays too little attention to the minute details of the technique and too much to the history of the injection method. A trained assistant is hardly necessary for so simple a procedure. In dealing with the submucous method of injection, injection above the haemorrhoid is not mentioned, neither is the combination of this method with injection into the pile mass considered. The author

states that the result of injection in third degree haemorrhoids is almost as good as operation, and places the number of cures of haemorrhoids by the injection method at 80 to 90 per cent. This is indeed optimistic! The section on operative methods includes a description of Whitehead's operation and the clamp and cautery methods, neither of which has a place in the modern surgery of haemorrhoids.

This book, though containing much in the way of repetition, will be of use to the general practitioner because of its easy and clear style.

INFECTIVE BULBAR PARALYSIS

La Maladie d'Aujeszky. By P. Remlinger and J. Bailly. (Pp. 202. 45 fr.) Paris: Masson et Cie. 1938.

Infective bulbar paralysis or pseudo-rabies was not recognized as distinct from rabies until 1903, when Aladar Aujeszky established its virus nature as distinct from that of rabies. It occurs among dogs, cats, cattle, pigs, sheep, and horses in nature, but man appears to be very resistant. The authors of this, the only existing monograph on the disease, have collected a few cases of infection, almost all very slight and abortive, in laboratory workers. This veterinary disease has an incubation period of from thirty hours to eight days, a short fatal course of three days, with a brief paralytic phase before death, which usually occurs during the night. An outstanding manifestation is pruritus, which in North America has earned for the disease the name of "the mad itch." In one of the human cases there was pruritus for two days; there does not appear to have been any fatal case in man. The authors of this monograph, who are in charge of the Pasteur Institute at Tangier, have contributed a pleasantly appreciative memoir of Aladar Aujeszky (1869-1933), a medical man and a veterinarian, author of 528 publications, professor of bacteriology, and director of the Bacteriological Institute of Hungary.

CARDIORADIOLOGY

Orthodiascopy. By Chester M. Kurtz, M.D., F.A.C.P. (Pp. 247; 67 figures; 31 tables. 15s. net.) London: The Macmillan Company. 1937.

With the development of cardioradiology to a point where it can be regarded as equal in importance to clinical and electrocardiographic methods many monographs dealing with this aspect alone are appearing. The subject is now a very large one, and an expert knowledge of the form of the heart in health and disease can hardly be attained except by those who limit themselves to this department of radiology. In his monograph based on 1,700 orthodiascopic examinations Dr. Kurtz first describes the techniques used, and includes a method for projecting the cardiac outline on the anterior chest wall, which, as he admits, may be omitted with little loss. The opportunity which such a projection gives the observer for checking his percussion findings will be welcomed only by those who still retain their belief in this clinical method.

In a chapter on heart size, comparison of the frontal cardiac area with the predicted normal, based on height, weight, and age, is preferred as the most reliable of the various methods of measurement, though it is pointed out that in border-line cases the method can only indicate the probable presence of abnormality or otherwise. The changes in rheumatic heart disease are well described, though the projection on the left border below the pulmonary artery commonly seen in mitral stenosis is referred to as the left auricular salient, while post-mortem observations show that this is usually formed by the conus of

the right ventricle. The section on aortic syphilis deals too briefly with the earlier lesions; in contrast to the great stress laid on cardiac measurement there is no reference to aortic measurement, which is admittedly difficult. In the final chapters coronary and hypertensive and congenital heart disease are very briefly considered. The aortic changes in hypertension appear to be regarded as predominantly due to dilatation, whereas the usual view is that an uncoiling of the arch is the important factor.

In this country, while radioscopy of the heart is being more and more widely used, the tendency is to use tele-radiographs rather than orthodiagrams when a permanent record is required, and the few radiographs reproduced in this book show their superiority to orthodiagrams. The monograph is suitable for those seeking an introduction to the subject, provided they shift the emphasis placed by the author on measurement of cardiac area to changes in form.

PUBERTY, NORMAL AND ABNORMAL

La Puberté: Etude Clinique et Physiopathologique. Edited by Guy Laroche. (Pp. 349; illustrated, 65 fr.) Paris: Masson et Cie, 1938.

This is a composite volume edited by Dr. Laroche, who contributes a chapter on normal puberty and its deviations from the normal time of arrival. Next is a chapter on sexual hormones and then one on pubertal intersexuality, the author of which concludes that there is normally an intersexual phase in boys but not in girls. This phase in boys may be characterized by certain physical characteristics, by a frank homosexuality, or by an indifference to the sexual object. From this phase originates almost all future sexual inhibition. In girls there is never anything but an indifferent phase which may accidentally produce homosexuality. He thinks the cause is almost exclusively endocrine. Then follow chapters on vasomotor and cardiovascular disorders, in relation to which it is necessary to distinguish between the rheumatic heart and the benign irritability of the adolescent's heart. Digestive disorders, tuberculosis, and goitres are dealt with, and then infantilism in the male and menstrual disorders in the female. The difficult subject of obesity at puberty is dealt with clearly, and the conclusion is that while many cases are due to a nutritive factor there is a group, often very difficult to treat, due to pituitary disorder, though chromophobic tumours are rare. The chapter on psychoneurosis is somewhat sketchy, and the author blames the instability of the environment, especially of recent years, as the chief causal factor. There are chapters on cellulitis, diseases of bones and ligaments, eye trouble, and skin reactions at puberty, and finally nutrition, physical exercise, and physiotherapy are discussed.

A book such as this may lack something of coherence, since it ranges over so many subjects. Nevertheless many doctors will find it a useful volume to have on their shelves, since it contains much useful information (which may be difficult to find in more orthodox textbooks) on subjects that must constantly crop up in day-to-day practice.

Notes on Books

Hearing: its Psychology and Physiology, by Drs. STANLEY SMITH STEVENS and HALLOWELL DAVIS, is published in London by Chapman and Hall at 22s. 6d. There have been greater contributions to knowledge concerning hearing in the last fifteen years than in the preceding fifty.

This book gives a valuable account of the present position in this field, which is on the borderline between physics and physiology. It is to be hoped that in the next decade it may prove possible to apply some of the new knowledge to elucidate the problems of deafness.

Dr. J. W. THORNTON, lecturer in pharmacology, Bristol University, has prepared imperial and metric conversion scales, constructed logarithmically from tables in the *British Pharmaceutical Codex*. Their purpose is to minimize the inconvenience caused to scientific workers by the simultaneous operation of the two systems of weights and measures. Quantities given in either system may be read at a glance in the other without need of tables or calculations. The seven scales on this one wall card cover all the everyday needs of doctor, dispenser, or research worker. It is published by John Wright and Sons Ltd., Bristol, price 6s., postage 6d.

Series XXXIII of *The Harvey Lectures* delivered under the auspices of the Harvey Society of New York is published at Baltimore by the Williams and Wilkins Company and in London by Baillière, Tindall and Cox, price 18s. The eight lectures in this series cover a wide field in physiology and allied subjects. Thus Selig Hecht, professor of biophysics, Columbia University, discusses the nature of visual processes, Einar Lundsgaard, professor of physiology at the University of Copenhagen, considers the Paster-Meyerhof reaction in muscular metabolism, and Dr. W. M. Stanley writes on the isolation and properties of tobacco mosaic and other virus proteins. Of more direct interest medically are Professor Goldblatt's account of experimental hypertension induced by renal ischaemia and Professor F. C. Koch's lecture on the chemistry and biology of the male sex hormones.

Preparations and Appliances

NEW INTRAVENOUS CANNULA

Mr. C. J. C. SIGGERS (Resident Surgical Officer, St. Mark's Hospital for Diseases of the Rectum) writes:

The cannula about to be described is a modification of that devised by Marriott and Kekwick. Their cannula was a great advance on previous designs, but the expanded tip was so large that it was very difficult to introduce into any but the largest veins. To facilitate the entry of the cannula into the smaller veins I had one made for me with a narrow extension beyond the bulb (see Fig.). This narrow bevelled extremity can be introduced into very small veins quite easily,

and once the tip is in the bulb will slip in without difficulty and the ligature can be tied behind it. A theoretical objection is that as the terminal opening is oblique it may be more easily occluded by the wall of the vein than if it were cut off square. Actually, this does not seem to happen in practice, owing probably to the fact that one is able to fix the cannula so that it lies in the correct alignment in the vein with the tip free. The diameter of the cannula at the tip is 2 mm. and at the widest part of the shaft 4 mm.; the length of those supplied has been just under 7 cm. Other sizes could be made to order, but this size will be found convenient in most cases. A larger size is not really necessary, and a smaller size should only be needed for babies and very small children. The cannula was made for me by A. L. Hawkins and Co., Ltd., of 15, New Cavendish Street, London, W.1.

MEDICAL ADVANCES IN SOVIET RUSSIA

At a meeting arranged by the Society for Cultural Relations with the Union of Soviet Socialist Republics, held at the Royal Society of Arts, London, on December 8, Major-General Sir CUTHBERT SPRAWSON, who paid a visit to Soviet Russia in the summer of this year, gave an account of his experiences there, particularly with reference to medical education and to the campaign against tuberculosis. He spoke as one who had been interested for many years in medical education in India, where he had been President of the Medical Council, and he found certain analogies between these two great, mainly agricultural, countries, both of which had been backward, though India, he said, was advancing slowly and Russia making rapid progress.

Medical Education

Sir Cuthbert Sprawson said that he was surprised to find one thing in common between Russia and India, in that both had a dual standard for medical education. In addition to the fully qualified graduates, both countries had a class of practitioners with lower qualifications, known in India as "licentiates." The origin of this class of lower status dated from the old army days, when most regiments going out on service did not have a fully qualified medical officer. The system was gradually abolished in the rest of Europe, but was retained in Russia, and up to the time of the European war this class of practitioner outnumbered the fully qualified in the proportion of three to two. The position now was reversed, and an endeavour had been made to abolish the inferior class altogether, but the shortage of practitioners was too acute to allow of this.

He went on to speak of the provision for medical students in Leningrad. In the institute which he visited in that city there were 3,000 students, more than half of them women. The institute had an attached hospital of 1,200 beds, and access to another nearly as large, but this provision did not seem enough for the teaching of 3,000 students. For the laboratory work the students were divided into batches, and four shared a single microscope. The position with regard to midwifery was easier, because every woman went to hospital for her confinement, and each student was expected to take ten cases before qualification. In the Soviet Union there were seventy-two institutes for medical undergraduates, not, of course, all as big as those in Leningrad and Moscow.

The Curriculum and Specialties

The time spent on the curriculum was shortened by earlier specialization in public health and hygiene, and the student taking these subjects was sent to a special institute for the purpose. During the first three years of the curriculum all the students did the same work; then they selected their special branch—general medicine, paediatrics, or public health—in which they continued for two years. But those who took public health continued at their special institute to receive instruction in general medicine also, though they did less clinical work than those who undertook the general medicine course. Of 25,000 medical students in the Union this year, 4,000 had chosen paediatrics, 3,200 public health, and the remainder general medicine. Students could, however, practise general medicine even if they had chosen one of the special fields, and the whole arrangement was in a state of experiment. The authorities admitted the disadvantages due to the present overcrowding, but it was hoped this might be remedied later and a six-year course (instead of the five-year course for full medical undergraduates) be instituted. The chief concern at the moment was to increase the number of qualified practitioners. In 1914 there were 25,000 graduate doctors; now there were 107,000, but these

in a population of 170 millions gave only one doctor to rather fewer than 1,600 people. The Government was aiming at one doctor per 1,000 of population.

In Russia there was only here and there any private practice; on the whole it was a State service. During his first year every doctor had to go where he or she was sent, and the best students were sent to the most out-of-the-way places, on the supposition that these people would be the most self-reliant. At the end of the year they could go, within limits, where they pleased, and there was no difficulty in getting them to go to the rural areas, for in the less desirable places the pay was higher, they had more holidays and privileges, and they were allowed to keep a car—and also a cow. There was excellent postgraduate training, and every doctor was supposed to have a refresher course of from three to six months every three years; how it was managed administratively he did not know. There were ten special hospitals in the Union for postgraduate courses.

Russia's Anti-tuberculosis Campaign

Sir Cuthbert Sprawson then gave some particulars of the "drive" against tuberculosis. The remarkable thing was that a notable decline in tuberculosis mortality had coincided with an increased industrialization and urbanization. The population of Moscow before the war was 1½ millions; it was now 3½ millions. In 1913 the tuberculosis mortality in Moscow was 22.6 per 10,000; it was now between 10 and 12. In Leningrad in 1913 it was 28.6, and now had been reduced to 12.0. In Kharkov in the Ukraine in 1923; when the campaign started, it was 17 per 10,000, and in 1937 had fallen to 12.0. As part of their third five-year plan the Soviet Government had set itself the stupendous task of halving the mortality of a chronic disease, but such surprising success had been made of it so far that one could not say it was impossible. The number of physicians employed in the sanatoria and tuberculosis dispensaries was 27,000, which meant that one doctor in every four in Russia was a tuberculosis specialist. Special tuberculosis teaching was given to all undergraduates, and postgraduate courses in the subject were given to 500 practitioners every year.

The institutional provision included central and regional tuberculosis institutes, sanatoria, special hospitals and special wards in general hospitals, labour prophylactoria (analogous to Papworth), and special schools for children. The sanatoria on the whole were like sanatoria anywhere else, and situated in attractive country. An interesting institution was the night sanatorium for patients who had had the disease and were back at work, but slept at the institution. The dispensaries were the front line of the attack, and there were 800 of these altogether in the Union. Their chief function was to detect early cases. The central and regional institutes directed the campaign, carried out research, collected statistics, published literature, and generally advised the units. Research was going forward with a view to finding out how much work a tuberculous patient could do. A good deal of use was made of B.C.G. as an immunizing agent, and some of the success of the campaign was attributed to that. In certain cities vaccination was compulsory for children likely to be exposed to infection. Altogether, Sir Cuthbert Sprawson left an impression upon his audience of an intensive campaign proceeding on many fronts, and one which, having regard to the vastness of the country and its recent backwardness, was being attended with astonishing success.

The nineteenth Salon des Médecins for the exhibition of works of art by doctors, veterinary surgeons, dentists, and pharmaceutical chemists will be held at 21, Faubourg Saint-Honoré, Paris, from February 19 to March 5. Further information can be obtained from the general secretary, Dr. Pierre-Bernard Mallet, 67, Avenue Pierre-Larousse, Paris.

SATURDAY DECEMBER 24 1938

ARTERIOSCLEROSIS

Since diseases of the heart and blood vessels now head the list of causes of death, chiefly because of the increased expectation of life brought about by improved hygiene, a new study of the biology of arteriosclerosis¹ is worthy of attention. The authors, who are members of the department of pathology of Yale University School of Medicine, have brought together an account of original work on the blood vessels and their diseases, when their structure is elucidated by the use of clearing agents of variable chemical composition. The dehydrating effect of glycerin, the defatting action of alcohols, ether, and benzene, and the decalcifying capacity of acids may be used either separately or combined. Injection may be carried out before clearing, and in this way the minute details of the vasa vasorum may be demonstrated. Investigation of the extent of these vasa vasorum in the past has given no clear indication of their relation to the nutrition of the vessel wall, either in health or in disease, extremes of opinion holding that they supply only the outer coats of the vessel walls, or, on the other hand, that they are responsible for the nourishment of all of the coats, including the intima. Apart from syphilis there appears to be no distinct cause for changes in the vessel wall, and the inability to reproduce the morbid process experimentally has led to the anatomical attack on the problem. Winternitz, Thomas, and LeCompte found that, using fresh material from the necropsy table, evidence was soon obtained that the diseased vessel wall is quite vascular. Minute haemorrhages and small capillary networks in the region of arteriosclerotic plaques were easily demonstrated by the use of injection and clearing methods on the aorta, the vessels of the extremities, the cerebral vessels, and the coronary arteries. Similar methods applied to the blood vessels of young people who had succumbed to injuries or diseases unrelated to the cardiovascular system showed the vasa vasorum to be by no means so readily demonstrable as in the diseased vessels. An extensive vascular network has been found by these workers in the normal blood vessels of a number of animal species, and

in the veins of human young people the vasa are exceedingly numerous. The origin of these anastomosing mural vessels has been traced from three separate sources—the adventitia, the region of orifices of branches, and directly from the lumen of the vessel. Blood capillaries are found running through all the coats of otherwise unchanged human vessels. The regularity of their pattern and arrangement points to their having at least a potential function in the walls of normal arteries. Loss of elasticity with age and the arteriosclerotic process are independent.

The cause of arteriosclerosis is unknown and is probably not to be found in one single factor. But an approach to the problem which is based on recognition of the artery as a vascular or potentially vascular organ, and therefore subject to the same pathological processes to which other tissues are subject, is the thesis which Winternitz, Thomas, and LeCompte have attempted to set up. Recognition of the existence of vascular channels in the wall of the blood vessel alters the conception of the reactions of this tissue to injurious agents. The response to injury is through the capillary bed and is manifested by two more or less distinct and variably proportioned reactions: exudation and proliferation. Exudation may include serum and cellular elements, and be further complicated by the precipitation of fibrin. Proliferation consists of new formation of blood vessels and connective tissue elements, including fibroblasts and many varieties of mononuclear cells. Evidence of mild exudation in the intima is not infrequent. These exudates are of little significance unless they are massive and cannot be removed promptly. Haemorrhage is but an exaggerated form of exudation and is readily recognized in the cleared tissue, because of the colour. It is common in the artery wall and is found in those places which are the site of predilection of arteriosclerotic lesions. It has been pointed out that the normal site of vasa vasorum and the network of capillaries which can be injected is at the origin of branches. This association of haemorrhage, vascularity, and arteriosclerosis cannot but be significant. The authors hope that their study will bring the subject out of the limbo of degenerations into the region of known biological phenomena. In the blood vessel wall, as in so many other areas where the inflammatory process manifests itself, the different elements of both the exudative and proliferative processes vary greatly, and the basis for the separate pictures must be dependent in part upon the specific chemical substances that are active. These agents may be limited in amount or may act as catalysts. They may be derived from exogenous agents, including parasites of various

¹ *The Biology of Arteriosclerosis*. By M. C. Winternitz, M.D., R. M. Thomas, M.D., and P. M. LeCompte, M.D. Baltimore: Charles C. Thomas, (4 dollars.)

kinds, or they may be endogenous—the product of cell disintegration or organ function. Such an endogenous agent or agents must be responsible for the closure of the ductus arteriosus; the similarity of this to the arteriosclerotic process is pointed out by the authors.

The problem of thrombosis is closely associated with that of disease of the artery wall. The various exudative and proliferative phenomena may take place in the vessel wall under an intima that is intact. Such diseases may be extensive enough to cause narrowing of the lumen, and fibrin may be deposited either within or on the surface of the intima. Careful study of the thrombi encountered indicated that the vast majority occur at the site of recognizable pathological change. Haemorrhage alone or associated with other change in the vessel wall is a common finding. The thrombus often arises as the result of injury to the intima, probably where the branch penetrates the aorta. Organization of the clot in the lumen of the vessel occurs, and it is suggested that the circulation may be restored, partially at least, by canalization of the clot with new vessels or by dilatation of the pre-formed vasa vasorum bringing about a collateral circulation in the wall of the affected vessel itself. The authors have produced a most interesting and suggestive monograph, and their demand that a revised attitude towards disease of the vessel wall should be adopted is likely to lead to much clearer definition of the problems of the biology of arteriosclerosis.

LIGHTING IN FACTORIES

The fourth report of the Departmental (Home Office) Committee on Lighting in Factories¹ is a thoroughly good document; and one that, if the recommendations contained therein are followed, will secure for workers and for employers real advantages. The report begins with a short historical survey. At the beginning of the present century, it says, very little was known about technique or measurement of illumination. That statement forgets the initial work done by school doctors; but so far as factories are concerned it is true. Credit is given to the initial work of Mr. A. P. Trotter of the Board of Trade, and Mr. Leon Gaster, the founder of the Illuminating Engineering Society. The report shows that industrial lighting conditions have improved on the whole and are still improving (especially with the readier access to gas and electricity in rural areas), but in spite of the facilities available many factories are still very badly lit.

Adequate lighting of industrial premises has been compulsory for many years in several countries, but in Great Britain for a few trades only of an especially hazardous nature. Vision depends first on light. But there are many other factors involved: the size and detail of the object, the duration of observation, the degree of contrast, colour, and the amount of light available. Modern lighting with its brilliant lamps has introduced a new difficulty. It develops contrast greatly, and an excess of this will cause the unsatisfactory conditions usually termed "glare." Bad lighting by daylight may be due to old and unsuitable buildings, obstructions of other buildings, dirty windows and dirty walls of the workshops. Bad lighting by artificial methods means too few or too weak sources of light, antiquated equipment such as naked fishtail gas-burners, dirty fittings, and absence of proper screens or reflectors. Statistical investigations by the committee have shown that accidents of certain types occur more frequently in winter months when daylight hours are fewer and when bad conditions of lighting prevail. Permanent damage to eyesight and to health can result from working in ill-lit places. Dark cooking places mean insanitary production. Good lighting has been shown to cause substantial improvement in discipline and moral behaviour. Lastly, the effect of bad lighting upon both quality and quantity of the work is extremely pronounced, and numerous scientific investigations have shown the relation between output and standards of lighting.

The recommendations of the committee are thoroughly sound and quite practicable. There is no place where they cannot be carried out effectively. Perhaps the most important, in view of the increased use of lamps of high specific intensity, are these: "(iv) Where any light source in a factory is less than sixteen feet above floor level, no part of the source or fitting having a brightness greater than ten candles per square inch shall be visible to any person whilst normally employed within 100 feet of the source, unless the angle of elevation from the eye to the source exceeds 20 degrees. (v) All local light sources in a factory shall be provided with suitable shades of opaque material or other effective means by which they shall be completely screened from the eyes of every person employed at a normal working place." It is to be hoped that the recommendations of this report will be carried out; the Home Secretary has the necessary power in the Factories Act, 1937, Section 5, which declares: "The Secretary of State may, by regulations, prescribe a standard of sufficient and suitable lighting for factories or for any class or description of factory or parts thereof, or for any process."

¹ H.M. Stationery Office. 1s.

PRISONS AND PRISONERS

The report of the Commissioners of Prisons and Directors of Convict Prisons for 1937¹ shows only a slight change in the number of receptions into prison. The total receptions of men were just over 42,000 and of women just over 5,000; the men showed a slight increase as against 1936 and the women a slight decrease. Only 19 per cent. of men and 10 per cent. of women were sentenced to imprisonment for more than three months. Most of the short-sentence prisoners had already been convicted, and the report is not a good advertisement for the constructive value of the prison system. The effect of the Criminal Justice Bill, when it becomes law, remains to be seen, and it will be decidedly interesting to compare the reports of a few years hence with this one. The new Borstal colony at Hollesley Bay in Suffolk came to life on May 2, when the first party of lads arrived, and the numbers are being increased as rapidly as possible, consistently with the need to build up a proper discipline and tradition. The main activity of the colony is fruit-growing, but it also has a large mixed farm. It has the advantages of being well away from any large centre of population and of providing much heavy and useful outdoor work. It is very big, and the Commissioners will be able to make the experiment of dividing the lads into five separate houses, each containing not more than sixty. The houses will be some distance apart and the lads will only go to the central building for purposes such as education and bathing. The New Hall camp attached to Wakefield prison now has about eighty resident prisoners, and parties of twenty are taken there every day. The men now breed pigs on the hut principle, keep poultry, and cultivate soft fruit. The report points with pride to the small figure for reconvicted prisoners since 1931—18 per cent. The figures for corporal punishment for prison offences show a progressive decline since the beginning of the century. In 1937 only two prisoners were so punished in convict prisons and none in local prisons. Under the extensive reorganization which is proposed the women prisoners will be removed from Holloway and the Borstal girls from Aylesbury. It is proposed to build colonies, preferably adjoining though completely separated, for these prisoners somewhere in the country near London. The aim is to provide institutions with opportunities for healthy outdoor work and exercise for as many inmates as possible. They will be housed in small groups, allowing better classification and greater individualization. The environment will be more open, and the Commissioners are confident of developing still further the ideas of training and reformation which have been devotedly pursued by the staff under the handicap of old and unsuitable buildings. The report contains an account by Dr. Mannheim and Mr. Dryden Donkin of their research into the records of Borstal institutions: this deals with causes of juvenile delinquency, and especially stresses the bad effect of fines, birchings, and short-term imprisonment. They

cannot confirm the popular belief that delinquency is caused to any appreciable extent by films, gambling, crime stories, or a number of other causes ascribed by popular belief. The report mentions with regret the retirement of Dr. W. Norwood East, the Medical Commissioner, who joined the prison service in 1899. Under his direction prison hospitals have been modernized, extended, and rebuilt. He fully recognized the growing importance of the psychological aspect of medical work in prisons, and under his wise guidance considerable advances have been made in recent years. He is even now preparing, with Dr. W. H. Hubert, a report on the results of the four-year programme of investigation and treatment for selected prisoners which he instituted at Wormwood Scrubs. He has been succeeded by Dr. J. C. W. Methven.

MEASLES VIRUS

The virus of measles is one of the most important of those agents causing disease in man, yet it is one about which comparatively little is known. Some authorities would even hesitate to place it in the group of filterable viruses, though that does not mean that there is any serious belief nowadays in the aetiological importance of the coecus of Tunncliffe or the micro-organism of Caronia. This hesitation is merely due to a lack of positive evidence, the direct result of not possessing a suitable experimental animal for measles research. And although Blake and Trask in 1921 left little doubt of the susceptibility of the rhesus monkey, the cost of these animals and the variability in their response to measles virus have proved a deterrent to their use in research. Had it been possible to grow measles virus in tissue culture with the production of some recognizable histological change, this might have compensated to some extent for the lack of a suitable experimental animal, and when, after the lead given by Goodpasture, use was made of the chorio-allantoic membrane of the developing hen's egg for the cultivation and study of viruses hope arose that this method might prove suitable for research into measles. This hope found some encouragement in the report by Wenckebach and Kunert¹ last year that measles virus could be grown in this way. So far, however, no confirmation of this work has been forthcoming. Plotz² now reports that he has succeeded in growing measles virus in a medium consisting of minced chick embryo tissue in Tyrode's solution with the addition of monkey serum: 5 c.cm. of minced embryo in Tyrode's solution and 1 c.cm. of monkey serum were placed in a 50-c.cm. Ehrlemeyer flask; 1 c.cm. of defibrinated measles blood and a few drops of hen plasma were then added, and the flask was closed with a rubber cork. Cultivation was at 37° C. with subcultivation every three days, 1 c.cm. of the ground-up culture being used to seed a fresh flask of medium. With the tenth subculture, which represented a dilution of 7⁻¹⁰ of the original blood, a rhesus monkey

¹ *Disch. med. Wschr.*, 1937, 63, 1006.

² *Bull. Acad. Méd.*, Paris, 1938, 110, 598.

¹ Cmd. 5868, H.M. Stationery Office, 1938. (2s.)

was inoculated subcutaneously, the dose injected being 5 c.cm. Ten days later the animal appeared ill, and there was an extensive maculo-papular rash which persisted for three days. The total white cell count, which had risen rapidly to over 30,000 after the inoculation, fell to 7,500 on the eighth day and persisted at this low level, the differential count showing a lymphocytosis; there was little pyrexia. Dr. Plotz believes that the monkey suffered from an attack of measles, and as the possibility of this being due to a residual virus is ruled out in view of the dilution of the original blood in the process of subcultivation, he is of the opinion that the measles virus had multiplied. The evidence in support of this conclusion is meagre, but Dr. Plotz is no doubt pursuing this line of work, and the results of a more extended series of experiments will be awaited with interest.

CARCINOGENIC HYDROCARBONS

There are three landmarks in the study of pure carcinogenic substances of known chemical structure—namely, the original demonstration of moderate carcinogenic activity in the pure hydrocarbon 1:2:5:6-dibenzanthracene, the identification of 3:4-benzpyrene as the carcinogenic agent in coal tar and, finally, the synthesis of the highly carcinogenic methylcholanthrene from bile acids. It is not proved that methylcholanthrene can be produced in the human body, but there is an evident possibility that if natural constituents of the body can provide starting-points for the laboratory synthesis of carcinogenic substances they might be transformed within the body into the same or similar substances capable of producing cancers of diverse kinds. These investigations initiated in London at the Royal Cancer Hospital are being vigorously pursued throughout the world, and recent reviews by Cook and Kennaway¹ and by Fieser² show how much has been, and how much remains to be, accomplished. Pure carcinogenic hydrocarbons, especially the three already mentioned, are in widespread use for the investigation of many aspects of carcinogenesis and open the way to more precise and quantitative experiments. The specialized chemical investigations are inappropriate for detailed analysis here, but some aspects deserve mention in general terms. A large number of hydrocarbons of related structure have been prepared and tested, and important progress has been made in the elucidation of the fine details of chemical structure which determine carcinogenic activity. It is now evident, however, that while most of the active substances so far examined are derivatives of 1:2-benzanthracene, this type of structure is not essential; compounds of widely different structure are carcinogenic. It is possible that carcinogenic power, though not dependent on a specific chemical structure, is determined by a particular kind of chemical reactivity shared by compounds of dissimilar structure. Early studies of the chemical properties of the carcinogenic hydrocarbons yielded no more clues to their mode of

action than did their chemical structures. Fieser records the beginnings of a more promising attack on this problem. It is known that the compounds undergo rapid change in the body; the chemical change, which may be small, apparently exhausts most of the carcinogenic substance long before tumours begin to appear, and may represent the first step in a complicated chain of events leading eventually to malignant growth. Fieser and his colleagues at Harvard found that the most potent carcinogens belonged to a small group of chemical compounds with unique chemical properties and surpassing all other known aromatic hydrocarbons in chemical reactivity of a special kind, notably a high degree of susceptibility to substitutions of a special type and to oxidation with lead tetra-acetate. Fieser suggests that the first reaction which occurs in a carcinogenic substance in the animal body might be one of hydroxylation or of the substitution of some related group, and that the introduction of an active functional group might provide a mechanism for the conjugation of the carcinogenic substance with substances present in the organism. As Fieser concludes, whether or not these speculations are valid, they suggest various lines of investigation which seem natural and worthy of trial.

RECREATIVE PHYSICAL TRAINING

The third annual report of the Central Council of Recreative Physical Training covers the period September 1, 1937, to August 31, 1938, and with excellent illustrations as well as in its text reveals the great efforts made by this organization to improve the physical and mental health of the community through physical recreation. Careful and systematic preparations were started to explore the possibilities of elaborating practical and comprehensive schemes in various parts of Great Britain which shall include all physical activities, both outdoor and indoor, and the requisite principles and details are now being formulated. Training courses for leaders have been organized and conducted, while some already in being have been stimulated and assisted, and grants amounting to £6,000 have been allocated to this council by the National Fitness Council. Pending the creation of more full-time salaried posts, the council has had to concentrate on the provision of short courses, mainly in the evenings or at week-ends or during the vacations. While forty of these were held in the year ending August 31, 1937, no fewer than 125 were held in the succeeding twelve months, and they were attended by between six and seven thousand men and women. Courses lasting three months were held at Anstey Physical Training College and Loughborough College for those who had already some knowledge of physical recreative activities. Some of these students have now returned to their home towns as organizers, while others are holding part-time posts. Men's training camps have continued to be a feature of the programme of the Central Council. Many demonstrations and lectures have been given, with follow-up work afterwards, so that enthusiasm may

¹ *Amer. J. Cancer*, 1938, 33, 50.

² *Ibid.*, 1938, 34, 37.

bear practical fruit. The report warns against the danger that demonstrations designed to stimulate "crowd emotion" may seriously mar the integrity of physical training as a means of recreation of brain and body, and as part of the general education of the adolescent and adult. Play leadership is regarded by the council as a logical and essential forerunner of the development of games for adolescents and adults, and four training courses and sixteen demonstrations were arranged during the year under review—for instance, one by 2,000 children was held in Regent's Park, London. The use of fields and spaces for recreation has to be associated with instructed leadership in the games and physical activities, and the Central Council sent representatives all over the country to examine possibilities and to advise. There is an obvious need for a larger and better central source of information on technical matters relative to physical education, and the staff of the Central Council are being kept very busy answering inquiries from all over the British Isles. The report (obtainable from the offices of the Central Council for Recreative Physical Training, Abbey House, Victoria Street, S.W.1) ends with a survey of what has been done in the various counties in Scotland and Ireland and the Isle of Man.

ACUTE INFECTIVE POLYNEURITIS

Widespread inflammatory and degenerative lesions of the peripheral nerves have usually been grouped together under the convenient term "polyneuritis." But apart from the polyneuritis caused by exogenous toxins little or nothing is known of the pathogenesis of most of the other conditions included under this designation. In a recent study of cases of polyneuritis called by French clinicians the syndrome of Guillain and Barré, or *polyradiculo-névrite avec dissociation albumino-cytologique*, several workers¹ describe the clinical features in detail, point out its possible epidemic occurrence, and discuss its pathogenesis and the differential diagnosis from poliomyelitis. In the cerebrospinal fluid there is always an increase of protein without any corresponding increase of cells. The almost uniformly favourable prognosis explains the absence of post-mortem observations. These cases have usually been included by English clinicians under the general classification of acute infective polyneuritis; some show a high cell count in the cerebrospinal fluid as well as increased protein, are relapsing in character, and often end fatally. Whether there is any pathological difference between this type and the syndrome of Guillain and Barré it is impossible to say in our complete ignorance of the pathogenesis. The present view is that they are all most likely the result of a virus infection. If so, it would seem that there may be different viruses or strains of virus having affinity for the peripheral nerves, and in that event the French are probably justified in regarding the syndrome of Guillain and Barré as a clinical entity. Several attempts to transmit a virus from these cases to animals have so far failed. There is need for further detailed pathological observa-

tions of all types of "acute infective polyneuritis." This has not yet been done, and the microscopical study of cases of peripheral neuritis has so far been much neglected. Such a study might reveal differences between the cases with dissociation of albumin and cells in the cerebrospinal fluid and those with abundant cells. Or it may be found that these variations are the result of different reactions of the host to the same virus. It may be noted that the administration of vitamin B has no effect in this group of cases and does not appear even to accelerate recovery. The observation by E. N. Rowlands and J. F. Wilkinson² that the values for the vitamin B content of the blood were normal in three instances of acute infective polyneuritis supports the view that deficiency in this vitamin is not an aetiological factor in these cases.

INDUSTRIAL PSYCHOLOGY

The eighteenth annual report of the National Institute of Industrial Psychology (Aldwych House, Aldwych, W.C.2) is a record of the many ways in which industrial psychologists can be of service to education, and it provides many examples of the practical value of this applied science. Serious financial difficulties were encountered during the year 1937-8, due to the rapid development of the work, much of which has to be financed from donations. Though at one time there was a danger that the work would have to be drastically curtailed, if not entirely stopped, these difficulties have been largely overcome, and the continuation of the Institute's activities is now assured. Advice on the choice of a career was given to some 1,400 young people, and a number of courses of training in the Institute's methods were held. The increasing use of intelligence tests in education is reflected in references to work carried out for education authorities in devising such tests. The studies made by the Institute on the heating, ventilation, and lighting of school buildings have developed steadily, and investigations were made for a number of authorities in different parts of the country. An inquiry into radiant electric heating yielded such interesting results that the manufacturers of the equipment asked the Institute to continue the work and to test new experimental types of apparatus. The result was that a new unit was evolved giving improved results and at the same time effecting a saving of more than 20 per cent. in current consumption. Research on vocational guidance, on the requirements of different occupations, and on the devising of new tests for special abilities was continued, and several extensive surveys of leisure occupations were carried out.

His Majesty has been graciously pleased to command that the British College of Obstetricians and Gynaecologists shall be known as the "Royal College of Obstetricians and Gynaecologists."

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation.

TRUSSES AND BELTS

BY

RALPH COYTE, M.B., B.S., F.R.C.S.

Taking first the subject of trusses, there are certain general principles which I think are of importance.

Type of Truss

The pad must be large enough to cover the opening through which the hernia protrudes, and it must be made from a material that is durable but not too hard, these qualities being most conveniently supplied by a form of cork. The spring must be of sufficient strength to keep the pad in position and prevent the hernia from protruding beneath it when any extra pressure (such as from a hard cough) is applied. To provide for the above contingency a steel spring is necessary, and, except in very special circumstances, I do not therefore prescribe any elastic or webbing truss. The spring must be covered by a material which is durable and comfortable, such as a soft kind of leather, the patient getting used to the pressure and no injury being done to the skin.

Truss for Inguinal Hernia

It is usually fairly easy to control this type of hernia by means of a truss, except when the protrusion is of considerable size. The pad of an inguinal truss fits snugly over the hernia, and when the hip is flexed the pad is forced more securely on to the exterior of the inguinal canal—a point of considerable importance, as we shall see later.

The plain pad of the inguinal truss will control any hernia that does not protrude beyond the external abdominal ring. In cases in which the inguinal hernia passes down into the scrotum or labia it is almost certain that a larger pad will be needed, and this is known as the rat-tail. The rat-tail is a prolongation downwards and inwards of the ordinary pad, ending in a thin strap which passes across the perineum up over the buttocks of the same side and fastens to a buckle fixed on the belt immediately behind the anterior superior spine. This type of pad will hold in place a hernia of considerable size, but when the protrusion passes down beneath it, it usually does so on the inner side, and the pad will then need building up on its internal aspect. This addition has led to a third type of pad which is known as a forked-tongue. The forked-tongue pad will hold in place the majority of herniae, but in some neglected cases and in old people with feeble muscles even this variety fails. To meet these circumstances several additions to the forked-tongue pad have been devised.

First, the pad, instead of being flat on the surface applied to the skin, is made into what is known as a prominent pad, and the surface then becomes cone-shaped, the apex of the cone fitting in the opening of the sac into the peritoneal cavity, in this way giving extra pressure with more hope of keeping the rupture in position. As a further measure, the placing of a steel spring in the pad, with its free end acting direct on to the hernia, provides still greater pressure. This addition is known as the concealed spring, and is the last hope of control by a truss except by making the actual spring of the

truss more powerful. When all these efforts have failed the only other instrumental help to be got is from a bag and braces. This appliance merely consists of a large bag, shaped to the hernia when the patient is in the upright position, the weight being taken over the shoulders by a pair of braces; the bag has an opening fixed at the level of the penis for purposes of micturition. It will take time for the patient to get accustomed to any of these forms of inguinal truss, and the wearer's grumbles during the first two or three weeks should not be taken too seriously. Certain precautions, however, should be taken: the patient should be watched for points of skin pressure, which will be shown by the appearance of sores. These are most likely to occur in thin patients, and the most commonly affected parts are over the spinal column and at the level of the anterior superior spine. Pressure over the spinal column can usually be relieved by fitting two back pads made of thick felt on to the inner side of the belt—one on each side of the spine. Pressure over the anterior superior spine usually means either that the truss is not of the correct size or that the outline of the patient is abnormal; in the latter case the spring, which should be made of a malleable steel, will need to be specially shaped to the patient. These difficulties, of pressure do not occur with trusses (usually proprietary) made with elastic belts, but my objection to these belts is that they do not provide enough pressure, except in the case of very small herniae, and even then the elastic so rapidly "gives" that the pressure very soon becomes inadequate.

In taking the measurement for an inguinal truss the tape-measure should fall into the hollow of the lumbar spine at the back and come round immediately below the anterior superior spine on each side, the ends meeting just above the symphysis pubis. In the case of children the truss should be rubber-covered to allow of easy cleaning, and very careful attention should be paid to the skin, with the aid of spirit and dusting powder. As there seems to be some confusion concerning the chance of cure of an inguinal hernia by wearing a truss I should like to say that it is almost non-existent after the age of 4; before that it is a very small chance, and depends on one very important point. This point, which must be rigidly observed if there is to be any possible opportunity of a cure, is that once a truss has been placed over an inguinal hernia no further protrusion of the rupture must be allowed until the truss is finally discarded, which may not be for several years. This means that if ever the truss is taken off a hand must immediately be placed over the hernia so that nothing is allowed to come down, and in addition the patient must sleep in a truss—conditions which make life very difficult. I have no hesitation in saying that a truss is not in any way a suitable method of treatment for an inguinal hernia unless there is a definite contraindication to operation. Most of us know how crippling a hernia can become in old age, sometimes making life a burden; consequently it is my practice to operate even up to quite a late age.

Truss for Femoral Hernia

In this type of hernia the question of easy control is not nearly so simple as with the inguinal variety, and for two reasons. First, a femoral hernia sac is frequently

surrounded by a very definite lipoma, formed from extra-peritoneal fatty tissue, and this prevents pressure being exerted direct on to the sac and gives rise to pain. Secondly, when the thigh is flexed, as in sitting down, instead of the pad of the truss being forced more securely on to the hernia it tends, owing to its anatomical position, to be lifted off the sac and therefore allows the contents to protrude. In this case the action of flexion will be seen to be exactly the opposite to that in the inguinal case. The type of spring should be the same here as in the inguinal truss; the pad is different only in that its direction is now much more downwards than in the case of the inguinal pad. In cases where an extraperitoneal lipoma is present a slightly cupped pad can be fitted so that the irreducible fatty tissue lies in this hollow and is therefore, so far as possible, not subjected to direct

Truss for Umbilical Hernia

This variety is very common, and is usually congenital in origin. The type of truss used for its control is again a steel spring, which at one end is beaten out into a thin plate. The whole truss is covered with a soft leather material and is buckled round the body at the level of the hernia, the fastening being placed on the external surface of the plate covering the sac. The truss as a rule controls the hernia with ease and is comfortable to wear. The difficulty arises when the hernia is irreducible, a not uncommon complication in long-standing cases; but here the steel plate can be cut away to allow the irreducible portion of the hernia to fit in the hollow thus formed, the pad then becoming a rim covered with material and shaped to the varying size of the rupture.

A.—Right inguinal

C.—Left forked-tongue.

B.—Right rat-tail.

D.—Right femoral.

pressure. This type of pad, which is known as the femoral hollow pad, prevents a considerable amount of pain, but is not altogether satisfactory.

In some instances a femoral hernia attains a considerable size, but it usually remains quite small even in old age. When the sac is a large one the pad will have to be increased to a size necessary to cover the opening in the cribriform fascia through which the hernia is protruding into the subcutaneous tissue. In order to keep this larger pad in position a leather belt, encircling the thigh from the pad and buckling back again to it, is usually fitted; it does not, however, add to the patient's comfort. The method of measurement for a femoral truss is exactly the same as that described for the inguinal variety.

Since the femoral sac is never seen in young children the problem here is entirely an adult one. The chances of a cure by the wearing of a truss can be said to be *nil*.

It will be gathered that in my opinion a truss is not a satisfactory treatment for a femoral hernia unless there is some very definite contraindication to operation.

If, as often happens, the umbilical hernia occurs in a patient who is also obese and requires an abdominal belt for general support, then the umbilical pad can be incorporated in the abdominal belt. The measurement for an umbilical truss is made straight round the body at the level of the umbilicus.

The chances of cure by the wearing of a truss in these cases is very small, although from time to time it does happen in infants. It is a curious fact that umbilical hernia is very common in newborn infants among the black races in South Africa, and although the condition is seldom treated in any way these herniae tend to disappear in the majority of cases; yet in this country, despite being kept in place by trusses, they have a great tendency to persist.

Abdominal Belts

What are the conditions for which abdominal belts are worn? First, there is obesity; secondly, very lax abdominal walls; and, thirdly, visceroptosis.

Obesity gives rise to abdominal pain owing to the weight of the overloaded omentum, and a belt designed

for this purpose will therefore need to lift upwards to some extent but at the same time must cover the whole abdomen, otherwise the fatty tissues are liable to bulge over the edges. The belt should be made of a strong durable material, with vertical bone supports incorporated; these must be well covered, or they will tend to stick into the patient. The belt should be quite tight at its lower border and somewhat looser above, as by this means the more pendulous lower parts are lifted and are fitted into the looser upper half of the belt. The measurements required by the instrument-maker for this belt are, first, straight round the body at the level of the lower border of the xiphisternum; secondly, a similar measurement at the level of the umbilicus; thirdly, one half-way between the umbilicus and the symphysis pubis; and, lastly, measurement at the level of the symphysis. The depth of the belt is taken from the tip of the xiphisternum to the symphysis pubis; the depth at the back should be about one-half of that in the mid-line in front. Fastening is done by a series of buckles, which in my opinion are more satisfactory if placed at one or other side than if in the mid-line in front. For extra strength a strap can be brought round from the mid-line at the back on each side and buckled to a right and left flap fastened to the mid-line in front; this is usually known as a yoke.

The belt provided for the *lax abdomen* is of the same kind as that just described, but as the condition is usually a result of multiple pregnancies and not necessarily a case of obesity, the effect is not so good as in cases of obesity alone, and in many such patients a repair operation is of much greater benefit.

With regard to *visceroptosis* one point of the utmost importance is that the diagnosis must first be clearly established by x-ray evidence. I see a large number of cases in which patients are sent up for a *visceroptosis* belt and in which the diagnosis has not been established, the real condition being something quite different. In cases of *visceroptosis* the aim is to give support to the lower half of the abdomen in an upward direction and thus hold up the sagging viscera. The support is usually provided by a suitably covered steel plate, which fills the whole space of the anterior abdominal wall below the umbilicus and is kept in place by two springs passing round to the back and fitting on to each buttock. For the fitting of any abdominal belt, most particularly that for *visceroptosis*, it is of great importance that the patient should be lying down, and if possible the head should be at a lower level than the pelvis. In this way the contents of the abdomen fall back into their normal or even into over-corrected positions, and if the belt is then fixed they are thus kept up. If, on the other hand, the belt is fixed when the viscera are already sagging, then the trouble is not only not remedied but tends to be exaggerated and the pain made worse.

Nutrition and Local Government—What Your Local Authority Can Do is a threepenny pamphlet published by the Children's Minimum Council (72, Horseferry Road, London, S.W.1). The problem of securing proper nutrition for every person in the country, and especially for the children, is now very much in the foreground. It has been extensively studied by the League of Nations, and the Government is concerning itself about the subject in various ways. It is less widely realized, perhaps, than it should be that even under the existing laws a good deal can be done to alleviate malnutrition, especially among mothers and children. This pamphlet sets out clearly what each local authority can do in its own area to help to solve the problem of malnutrition.

Nova et Vetera

THE MEDICINE OF OUR ANCESTORS

Some Old MSS.

Two rather quaint old medical manuscripts were sold at Messrs. Sothebys in Bond Street on December 14. One consisted of a bound volume of treatises in various languages (English, French, Latin) and by different hands: the first and longest of the collection is a treatise on surgery, which runs to 161 pages, plus an appendix on the compounding of remedies. Chapter I is headed "Of a Phlegmon," and begins:

"A Phlegmon or inflammation is a very sensible swelling of some part with a redness, heat and pain of ye same, and often is accompanyd with a fever, all which is caused by an extravasation of the blood. The causes are a thick and sometimes a rarefyd violent mould and fermentative blood which meeting with some resistance in ye smaller vessels or being more thickened or rarefyd in some places than others it stops in ye blood vessels and so hinders yt that follows to circulate which distending the membrans of ye arteries or veins at last burst 'em and overflows betwixt ye fibres or membrans of some fleshy part which it distends and elevates and is called a phlegmon. A phlegmon is produced also by any external or internal pungent irritation inasmuch as it produces a violent influx of ye spirits which contracting ye fibres of ye part chokes up ye passage of ye blood, or it may cause a phlegmon by rarefying ye blood more than ordinary, as smoke for example causes an inflammation of the eye. A coagulated lymph of the arteries and veins may cause a phleg: or any external cause pressing on ye extremity. . . . As for the cure, let ye patient be blooded as soon as can be by which the growth of ye swelling will be hinderd and the fever deminish'd."

The author further advises free purgation, though he adds that some authorities are very much against it. It seems a legitimate deduction that the writer knew and freely accepted Harvey's teachings on the circulation; so the date of the manuscript is probably of the seventeenth century. The handwriting is very similar to that of a later MS. in the series which is dated 1682, though it is hardly possible to say they are certainly by the same hand. Following a treatise in French on poetry, one comes to what would appear to be a copy of a letter to a patient about some affection of the breast—perhaps a malignant growth.

"The oppresion of your breast and extenuation of your body seems to proceed from the acrimony or sharpness of your blood which passing through the louns that are of a very delicate contexture corrodes or irritates the parts thereof: wherefore the chief thing one shoud aime at in the curreccion is to sweeten the blood and give it a natural consistence and more proper to nurish the body. For these ends I think fit she shoud make use of the insuing remedies. First 't will not be amiss to let out a small quantity of blood, both because the remedies so will have more roome to operate their effects as also to hinder any vain or blood vessel may be in danger to be opened in the lungs or in any other place. Secondly to evacuate in some manner ye acrimonious humours in the blood 't will be fitting to take some very mild and gentle purge, for example a little mann in broth or with a pectoral decoction as follows. . . . A day after this she may make use of these pectoral pills for ten days" [liquorice, hyssop, prune, prescribed for pills]. "After this I think 't woud be fit she shoud purge herself as she did before and a day after use ye following broth composed of crayfish of the river which are very much in use in all maladyes coming from ye sharpness of the blood."

The MS. goes on to advise a milk diet for a month and a half, with oatmeal, etc.

"Charmes" Against Sickness

The other old medical manuscript is of date approximately 1475 and consists of fourteen leaves of medical and domestic recipes in English, with a list of "charmcs" to ward off sickness, some of them in Latin. The handwriting

is much like black letter print, and is beautifully done. A transcript was sold with the original, prefixed to which is a charm, also of 1475, for a lying-in woman. "For woman that travelyth of chylde bynd this wyte to her Thye," followed by a Latin prayer or adjuration to St. Elizabeth and other personages. Another is "flor to staunche the flux take hoot mylke as yt comyth fro the cowe and put in a veselle and tak as moche 7 of myntes and put in a nother vessell and tha put a pype in 7 be yt self and drink up at onys both lyeours wt the pyper. Use this in tymys, and he shall be hoole." Next is "flor worms in a manys wombe take iii days fasting a drawth of swet mylke as yt comyth fro the cowe and at the iiii daye yewe hym to drynk parlyk and stamp yt wt wyneure lowke warme. Also drynk coole seed or achse seed. . . ." Others of the headings are "A good Charme to staunche blood," "A Charme of Sent Sovera," "A Charme for wyked wyts."

SECTIONS OF A MUMMY

The Histology of Har-Mosë

About the end of the fifteenth century before Christ there died in Thebes a great architect, Sen-Mût, who had carried out much of the magnificent buildings for the warrior queen, Hatshepsût, and in particular the famous temple at Deir el Bahri in the Valley of the Tombs of the Kings. While Sen-Mût's rock tomb was being dug and while his body was undergoing the first and most costly method of embalming, it happened that a poor old singer named Har-Mosë died; he bore some relationship to the great architect, but whether he was in his service or that of a relative is not known. There was no family tomb to receive him, and so after a simple embalming his coffin was placed in a gully near his patron's tomb, his lute was laid by his side, and his entrails, which had been soaked in salt, were wrapped in linen and placed in an ordinary household box, roughly converted to a Canopic chest. In 1935 Mr. Lansing and Mr. Hayes came upon this mummy when excavating at Sheikh Abd el Kurnah, and they sent it to the professor of anatomy at Cairo, Dr. Derry, who found the skeleton in poor condition. But the entrails appeared unusually well preserved, and were dispatched to Professor A. F. Bernard Shaw, who has recently given an account of his observations.¹ The founder of palaeopathology, Sir Armand Ruffer,² has given numerous accounts of pathological lesions found in mummies, but the histological methods which he employed were limited, and he had considerable difficulty in cutting sections until the material had been softened in sodium carbonate. In the case of Har-Mosë Professor Shaw had no difficulty in cutting sections embedded in paraffin in the ordinary way, and applied the full armament of modern microtomy. His results are truly remarkable. All the organs could be readily recognized and their pathology studied. It is true that all nuclear material had disappeared and much of the cytoplasm, yet the acellular stroma—the collagen, elastica, and in particular the reticulin network—showed no detectable change, and it was this that enabled an accurate study to be made. Professor Shaw concludes that Har-Mosë was a fat man who suffered from emphysema and probably died from a severe bronchopneumonia with pleurisy. It would appear that the air of ancient Egypt was not so pure and balmy as we have been led to believe, for there was much anthracosis in the old singer's lungs. The most striking feature is the perfect preservation of the minute reticulin fibrils; their mode of formation and chemical nature are still in doubt. They cannot be demonstrated with ordinary aniline dyes, but must be impregnated with silver to render them visible—and this was possible after over three thousand years.

MEDICINE AND THE LAW

LORD DAWSON'S SPEECH

The annual dinner of the Medico-Legal Society was held at the Connaught Rooms, London, on December 16, with Mr. JUSTICE HUMPHREYS, president of the society, in the chair. The company was representative in about equal parts of law and medicine, and the usual toast of the two professions was given in a witty speech by Sir ROBERT H. PICKARD, Vice-Chancellor of the University of London. He suggested certain analogies and contrasts between the two professions, as, for example, that the wise man went to medicine quickly and to law slowly.

The Shackles of Law upon Medicine

VICOUNT DAWSON OF PENN, in responding for "Medicine," said that the law had been built up, like a happy synthesis, by a succession of individual judges, and thus, in the curious English way, from time to time there crystallized out rules and principles which acted as guiding posts for years to come. The law in this country was dynamic, it was sensitive to prevailing standards of conduct and progress of knowledge. "A striking example of that, as I see it, is afforded by a study of the pronouncements on the law relating to abortion extending over the last seventy years. They have gone on step by step, always a little behind, as is proper for the law, because medicine in its advance, I must admit, has a frayed edge, and the law cannot afford to have a frayed edge, it must have a sharp outline. But we have lately had a pronouncement which I venture to think is epoch-making [Lord Dawson was evidently referring to the summing-up of Mr. Justice Macnaghten in the trial of Mr. Aleck W. Bourne at the Central Criminal Court], amongst other reasons for this, that it is the first time that health has been correlated in relation to quality of life as distinct from quantity. . . . This judgment has brought to the fore that health means quality of life."

The law had the defects of its qualities, Lord Dawson continued, and it was sometimes found that judgments pronounced in other days and under other conditions resulted in some retardation of progress. It should also be said, however, that the law had always paid regard to the interest of the community, and not only to retribution and reformation of offenders, while medicine, until relatively recent times, had been held to concern itself with the individual patient and his immediate sickness. To-day medicine took and was expected to take the wider view of prevention and deterrence of disease in this and the next generation, but here it might find itself in conflict with the laws concerned with maiming, unlawful wounding, and bodily harm. In the case of persons of mature age who wished to marry, one of them being unfortunately liable to transmit disease, why should not he or she, on request, be allowed to be sterilized? He instanced the case of a woman who was a carrier of haemophilia. Another example was the carrier of typhoid, with the typhoid germ, there was reason to think, residing in the gall-bladder. Yet the removal of the gall-bladder might be regarded as unlawful wounding.

"Such shackles, never intended to apply to us, should be removed so that medicine may be set free to extend its ever-widening work of preventing disease. It would be an appropriate task for this society to set up a committee to consider how, with reasonable precautions, we may bring these laggard little bits of law up to date, and make them, as most of the Common Law already is, in tune with the advance of knowledge and the public conscience."

Lord Dawson also referred to the Criminal Justice Bill. There were a number of offences, he said, which had "one foot in pathology and one foot in crime." These cases required treatment as well as punishment. The proposals embodied a considerable extension of the range of probation which enabled treatment to be carried out

under the guise of punishment. He hoped there would be, in this field as in others, a great advance, but if mistakes were to be reduced to a minimum and success made more real there must be co-operation between the medical and legal professions.

The Unchanging Common Law

Mr. JUSTICE MACNAGHTEN, who responded for "Law," said that in view of Lord Dawson's remarks about the Common Law, he felt called upon to make some answer. Mr. Justice Humphreys and he were but servants of the Common Law, and he thought they both would resent any suggestion that the Common Law changed with the changes of popular emotion. On the contrary, the Common Law, founded on the common sense of the people of this country, was unchangeable and unchanged save in so far as Parliament, in its wisdom, or otherwise, saw fit to alter it. It fell to his lot this year to expound the law relating to the procurement of miscarriage, and he did no more than state to the jury what Mr. Justice Humphreys, as president of that society, had explained on a previous occasion.

"So far from it being true that there has been any change in the law," Mr. Justice Macnaghten continued, "the law of England on that subject has always been the same. Much of the criminal law is founded on the very simple Ten Commandments, or such of them as are applicable, and one of them is 'Thou shalt not kill.' The law that said 'Thou shalt not kill' applied also to the unborn child as it did to the living human being; but if the choice came between the life of the unborn child and the life of the mother, the Common Law of England said that the life of the mother was to be preferred to the life of the unborn child. In that, I understand, it differed as in other respects from the Canon Law. I am told that by the Canon Law the life of the unborn child was to be preferred to the life of the woman, but the Common Law of England preferred the life of the mother.

"In those days, long before Parliament ever existed (because the Common Law is much older than Parliament), medical science had not advanced so far as it has now, and it was supposed that the child was not alive until it gave some manifestation of its existence. The result was that in a prosecution for killing an unborn child the prosecution had to prove that the child was alive, and obviously there was great difficulty about that. The woman herself, no doubt, would not be a very willing witness. Parliament, in its clumsy way, at the beginning of the reign of George III, passed a law to make it a crime to procure miscarriage, even if the woman was not pregnant at all, and so it came about that there was a popular superstition that in all circumstances the procuring of miscarriage must be illegal. But the Common Law remained the same. It was always lawful to kill the unborn child if it was necessary to do so for the preservation of the life of the mother. And by preserving the life of the mother it did not mean preserving her as a lunatic or as an absolute physical wreck, preserving what was not really to be called a life at all. That, under the guidance of your president and my teacher, was the law which it fell to me to expound to the jury, and so it is thought by some who do not know—amongst whom I must not include Lord Dawson of Penn—that the Common Law of England has changed. On the contrary, the Common Law of England, founded on the common sense of the people of England, has always been the same, and if you trust to it you will be safe."

Mr. ST. JOHN G. MICKLETHWAIT, chairman of the Middlesex Sessions, proposed the health of the society, to which the PRESIDENT responded, remarking that the society was in a flourishing condition with 400 members. He referred in detail to its programme of meetings and its honorary officers. The toast of "The Guests" was proposed by Judge LEIGH, president of the Manchester and District Medico-Legal Society, and brief responses were made by Professor W. H. ROBERTS, president of the Society of Public Analysts, and Miss ELIZABETH BOLTON, president of the Medical Women's Federation.

MEDICAL USES OF RADIUM

THE M.R.C. REPORT

The sixteenth annual report on the Medical Uses of Radium, issued by the Medical Research Council,¹ must not be confused with its report on Radium Beam Therapy, which has already been reviewed in this *Journal* (December 10, p. 1209). The report now under consideration deals with the work carried out at the various centres which hold radium on loan from the Council, and, like its predecessors, consists of an experimental and a clinical section. Year by year the space allowed to experimental work has gradually increased, and this year the two sections are of approximately equal length.

A glance at the experimental section will show the wide field of research which is being covered. In the domain of pure physics Professor Paneth deals with the production of neutrons—that is, particles of unit atomic weight 1, but carrying no electrical charge—which promise to be of no inconsiderable practical importance in the near future—and other aspects of the same, subject are considered by Mr. Saxton and Mr. Michiels. Professor Hopwood is investigating the physico-chemical effects of neutrons and gamma rays; he has already established the facts that (a) the effects due to neutrons are of the same nature but relatively far more powerful than those due to gamma rays; (b) negatively charged colloidal particles become more stable, and positively charged colloids become less stable, when irradiated with either neutrons or gamma rays; (c) over a wide range of exposures the breakdown of dilute aqueous solutions of hydrogen peroxide and the oxidation of dilute solutions of potassium meta-bisulphite were directly proportional to the number of neutrons captured or of gamma-ray energy absorbed. The whole series of experiments supports the view that the primary action of the radiations is on the water, and if this view is correct the role played by water in the animal body must be significant and possibly predominant.

Dr. Mayneford reports further progress in the work of standardizing gamma-ray dosage in terms of *r* units. This is, of course, of the first importance in estimating the all-important question of dosage in radium treatment.

Research on Gamma Radiation

Dr. J. C. Mottram reports some results on the combined action of gamma radiation and the carcinogenic hydrocarbon 3:4-benzpyrene. Four batches of twenty mice each were painted with the benzpyrene once a week over seventy-five days: one batch served as control, the remaining three received doses of 1,440 *r*, 480 *r*, and 160 *r* respectively about the sixteenth day. In the control batch five warts developed; in the 160 *r* batch, six warts; in the 480 *r* group, thirteen warts; and in the 1,440 *r* batch, fifteen warts. It had been reported by Cramer that doses of 4,400 *r* and 8,800 *r* applied to mice similarly painted delayed or inhibited neoplastic formation. The general conclusion reached is that while larger doses of gamma radiation inhibit the further development of precancerous lesions, insufficient dosage to the whole or part of the lesion may increase the tendency to malignant change.

Dr. Joan Ross had already shown that a weak gamma-ray source acting for a long enough time is carcinogenic for the rabbit. The source employed was 0.5 mg. screened by 0.55 mm. platinum, and the tumours appeared at an average of 125.5 weeks after its insertion; as the first tumour had already attained a large size at 97.5 weeks, ninety weeks was considered to be the earliest time of expectation for tumour production. Subsequent experiments have been conducted with the same radium needles, but a modification has been introduced by the

¹ *Medical Uses of Radium*. Summary of reports from research centres for 1937: Medical Research Council. Special Report Series, No. 232. H.M. Stationery Office. 1s., postage extra.

injection of Shope's papilloma virus and infectious fibroma virus into two different series of rabbits, in order to see if the time necessary for the development of the tumours could thereby be reduced. It is too early to draw conclusions, but one rabbit in each series developed a tumour from sixty to seventy weeks after radium nuplantation. These experiments are being followed by further series.

Professor Russ and Miss G. M. Scott again report upon some biological effects of prolonged exposure to gamma radiation. Young male and female rats were exposed to forty-seven times the "toleration dose" on 121 days, with two free days each week.* After this exposure both males and females were rather lighter in weight and had a much higher death rate than the controls. This lag behind normal weight was never made up, when the rats were 1 year old the controls were fine healthy animals, but the irradiated rats mostly died young, and the survivors were thin and prematurely aged. The females when mated to normal males became pregnant, but in only one case did the young survive birth for any length of time. The rest died at birth, were born dead, or abortion occurred. Male irradiated rats mated to normal females were sterile for several months. Four months after the end of irradiation two surviving members produced apparently healthy offspring by their control mates. Further important contributions to the experimental work are made by Dr. J. G. Spear and Dr. C. B. Allsopp of Cambridge, as well as by Dr. M. A. C. Cowell of Manchester.

Clinical Work at the Centres

In the clinical section there are no striking new developments to record, but the usual standard of excellence is maintained at the Council's various centres. At the Birmingham General Hospital special attention has been paid during the past year to radium dosage in cancer of the breast, and Sievert chambers have been introduced as part of the routine clinical practice. At the Marie Curie Hospital cancer of the corpus uteri has hitherto always been treated when possible by operation, and radiotherapy reserved for those cases in which it was contraindicated on general grounds or when the patients refused operation. These cases treated by radiotherapy alone have, however, proved of considerable interest, and the results suggest that this may after all be the best treatment in all cases of cancer of the corpus, except when it is complicated by the presence of myomata or ovarian tumours, and possibly when pelvic inflammatory disease is present. The five-year survival rate is found to be approximately the same for radiotherapy as for surgery, while the distress to the patient is much less and the mortality should be *null*. Cancer of the oesophagus is treated at the Middlesex Hospital by using radon mounted on Souttar's tubes, a dose of 3,000 *r* being given to the mucosa over five days, during which time the patient is fed by a stomach tube passed through the nose and the Souttar's tube. This procedure has been found to improve the general health, to avoid the necessity for a gastrostomy, and to relieve dysphagia during subsequent x-ray therapy, which is still considered to be the best treatment at the hospital's disposal.

Radluthery for Metrorrhagia: A Warning

The Marie Curie Hospital issues a timely warning respecting the radiological treatment of metrorrhagia in young women. It is a matter which has several times been referred to in this *Journal*, and we are glad to find it attracting attention at this very important centre. The passage in question is well worthy of quotation:

"Researches on the hereditary abnormalities following experimental irradiation of some animals may have a bearing on the radiological treatment of haemorrhage in young women.

* The International Committee of Protection recommends that no one working seven hours a day should be exposed to a greater continuous intensity of radiation than 10^{-4} *r* per second, which is three times the toleration dose.

If it can be shown that a small radiation dosage, such as is given in these cases, may cause gene mutations which are irreversible and may be inherited, these results will have to be considered in relation to the treatment of haemorrhage in younger women. As there has been only one generation since radiation began to be extensively used in these cases it is doubtful if sufficient data for an investigation of the effects on human heredity are yet obtainable. It is important that all women of child-bearing age receiving radiation treatment should be kept under observation and their descendants followed up."

The comparative brevity of the clinical section is to be taken as an indication that procedures are gradually becoming standardized, so that there is now no need for the repetition of detailed descriptions, and a considerable part of this section is occupied by tabular summaries of the results obtained over several years.

AIR RAID PANIC

DISCUSSION BY BRITISH PSYCHOLOGICAL SOCIETY

A discussion on "Panic and Air Raid Precautions" took place at a meeting of the Medical Section of the British Psychological Society on December 14, Dr. E. A. BENNETT presiding.

Dr. JOHN RICKMAN, physician of the London Clinic of Psycho-Analysis, said that air raids must be regarded as an attack on the nerves of the civil population. The method might be new but the problem was familiar. Not everyone in such an attack showed signs of panic, and the resistance of the individual differed at different times. Panic might be defined as a condition in which the highest degree of dread was experienced, social ties being temporarily severed and self-control abandoned. External danger obviously played a part, but there were other factors, and indeed external danger mobilized the aggressive impulse. He described two stages of panic. The first was characterized by a feeling that self-control could not be maintained much longer, but it passed off if danger lessened or moral reinforcements arrived, otherwise it might develop into acute panic with loss of control of mind and body. It was during this stage that individuals "broke formation" and ran from their friends, but the capacity of response to leadership need not be lost. A calmer stage might follow, with return of self-control and loss of restlessness, but response to command would still be feeble and the sense of belonging to a group would be imperfect. In a further stage the panic might resolve itself, so that there was resumption of social contacts and return of self-respect. The most important factor in preventing panic was the building up of self-confidence, identification with a strong parental figure, firm and decisive leadership. Dr. Rickman concluded that there was not one cause of panic but a multitude of aetiological factors, not one stage but at least three, and that the endeavour to foresee and prevent what might prove to be the greatest menace of modern war was no reflexion upon the quality of British people; to gloss it over would be a failure of medical duty.

Psychological Defences

Dr. E. B. STRAUSS, physician at the Institute of Medical Psychology, said that air raids were aimed at the destruction of civilian morale. It was war waged against the mind, as, in the last resort, all wars were. It had become a cliché that spiritual disarmament must accompany or precede material disarmament; it was not as generally recognized that the converse was true—that psychological as well as material defence must be looked to. Psychiatric casualties in air raids would tend to fall into two main groups. Some people would run riot and others be rendered immobile by shock, and each group would require

to be differently handled in the interests of the individual and to prevent spread. It was impossible to estimate the proportion which such casualties would bear to physical ones in a future war, but the Spanish experience seemed to show that the population became accustomed to air raids and the number of acute psychiatric casualties became progressively less at time went on. Prophylaxis seemed likely to depend on one principle—namely, inculcation of group loyalty and sense of common aim. With the passing of the "old school tie" spirit psychological defences were impoverished, and the decline of the belief in revealed religion had left another gap. Group psychologists in certain countries had discovered that the quickest method of uniting a nation was by the inculcation of a common hate; a common love did not seem to have the same dynamic result, and yet this was likely to be a much more reliable spiritual defence in the last analysis. One important thing was that every citizen should have his particular duty allotted to him beforehand. A knowledge of what to do and where to go to do it was the best preventive of panic and neurosis.

Spanish Experience

Mr. JOHN LANGDON-DAVIES described recent observations in Spanish bombarded towns, where, after more than two years of air war, the morale of the Government supporters was unimpaired. One of the most important reasons for this was the sense of solidarity between the Government and the governed. There was no suspicion that the Government had kept the people in the dark. He pleaded for a similar frankness here. The people must be made to understand that London in air war would be the front line. A.R.P. should consist, not in fantastic instructions about gas-proof rooms, but in evacuating the people who were not suitable for front-line experience. No air raid was likely to direct attention to what were called military objectives. The only objective of air bombardment was the nerve centres of the population. It was necessary to prepare the people for a possible experience of successive bombardments at unpredictable intervals. As a relatively minor matter he complained of the wailing note of the sirens which were to give the air raid warning. The sound was a frightening one, whereas it should be a call to action. People who had a definite job to do in a raid were in a much better psychological condition than those who had not. The paralysing effect of noise in itself had also to be considered. To the nervous person the psychological damage, owing to the noise, would be equally great even though every bomb were blank. The wireless might be largely employed in calming the fears of the population due to the noise of the anti-aircraft guns.

Reactions in Different Types

Dr. DENIS CARROLL doubted whether the stages in panic were as clear-cut as Dr. Rickman had suggested. The earlier stages might represent only fear and anxiety. It was not proper to speak of panic until control had been lost in some degree. The actual factors concerned were both objective and subjective, of which the latter were the more important. The objective factor might be no more than a trigger mechanism. With a normal person presumably a much greater objective stimulus would be required. Psychotics did not panic as much as hysterics, and during the last war it was shown, both on active service and at home, that the psychoses were not increased in the same proportion as the neuroses. He agreed with what had been said about strengthening the ego by providing an ego-ideal. It was important to find an outlet for the aggressiveness which was stimulated as the result of air attack. This was most properly channelled in active or auxiliary services, but if it were not given some outlet it was liable to express itself against others in the crowd. Among certain practical suggestions he welcomed the idea of the large provision of under-

ground shelters, but said that it was important to equip them with sufficient inlets and outlets and ventilating shafts, not only for ordinary purposes but to prevent the claustrophobic reaction.

In the course of some general discussion Dr. MARGARET LOWENFELD referred to the need for recharging the morale between bombardments, and to what teachers and others could do in this respect in persuading people to undertake some creative employment instead of merely listening to others. Dr. BERNARD HART expressed himself sceptical as to whether there were fundamental differences between the Spanish and English temperament in regard to blood and death which one speaker had suggested. Dr. ROSS thought that the evacuation of women and children might be desirable from the point of view of the morale of the men, who would be less likely to suffer from the anxiety state if their dependants were not imperilled. He also mentioned that the reaction of many people to air raid bombardment would be not panic but the not unrelated condition of elation. Another speaker referred to the importance of adequate medical services from the psychological as well as from other points of view. A breakdown of medical services would be a primary factor in precipitating panic; their efficiency and adequacy would be a primary safeguard.

FAR EASTERN TROPICAL MEDICINE CONGRESS

The tenth congress of the Far Eastern Association of Tropical Medicine was held from November 25 to December 10. The meetings took place in the Medical School of the Hanoi University, a school which has a course and gives a diploma to its students, enabling them to practise without further examination in France. It is thus comparable in standard to the medical schools in Singapore and at Batavia. Many of the students go home to specialize and take degrees at French universities. The Governor-General, His Excellency M. Jules Brevié, opened the first meeting of the congress in the grand amphitheatre of the University. The president was Dr. Le Roy des Barres, professor of radiology at Hanoi, who is also known as an eminent public health officer. The British vice-presidents included Dr. Selwyn Clarke, Hong Kong; Dr. A. L. Hoops, C.B.E., Singapore; Dr. R. D. Fitzgerald, Malay States; and there were vice-presidents from India, Burma, and Australia, and Dr. Park from the League of Nations. Dr. H. C. Smith represented the United States, and Dr. Larsen, Honolulu. There were large delegations from most countries in the Far East, including China and Japan, the Dutch East Indies, the Germans in China, and small delegations from India, Burma, and Australia. The German delegation included one surgeon from Shanghai.

Hanoi, the capital of French Indo-China, is a town nearly as large as Singapore but not so up-to-date. French Indo-China is an extensive territory comprising two French colonies, in and around Hanoi and Saigon, and a number of native States with governors or residents serving under their native rulers. It may be compared in constitution to the Straits Settlements and Malay States, and to the colonies and native States in the Netherlands East Indies. Like them the natives are now being given a responsible share in the Government. The country is some 2,000 miles long and about 500 miles wide in its widest part. It borders on Siam, Burma, and the South China province of Yunnan and is not far from Hong Kong.

Dr. Hoops has been asked to visit Yunnan-fu, the capital of Yunnan, about 400 miles from Hanoi, to report on the casualties inflicted on non-combatants recently by Japanese aeroplanes operating from the region of Canton; also to inspect the medical arm of the Chinese force at Yunnan-fu and report on deficiencies of medical stores and equipment. Dr. Hoops will return to Singapore, travelling through Burma, and looks forward to sending adequate medical supplies from the Chinese War Relief Committee of Singapore.

LONDON JEWISH MEDICAL SOCIETY

Appeal for Refugee Doctors

The eleventh annual dinner of the London Jewish Hospital Medical Society was held at the Trocadero on December 18. Professor Henry Cohen, who was in the chair, in proposing the health of the guest of honour, Dr. Robert Hutchison, P.R.C.P., said that the Society met that evening with their hearts heavy on account of the position of people of their race in Central Europe. The spurning in Europe of freedom of thought and of conscience was a challenge which they as Jews must meet. Professor Cohen then paid a glowing tribute to the personal and professional qualities of Dr. Hutchison, whose medical career, he pointed out, had coincided with the great modern discoveries in medicine.

In response Dr. Hutchison said that he was particularly glad to be honoured by a Society in which he had so many old friends and whose members belonged to a race to which the science of medicine owed so much. In proportion to its numbers no race had contributed so freely to medicine, especially during the past fifty years. The Jews and the Scots, he considered, had many qualities in common, such as devotion to education, awareness of the value of hard work, and a capacity for getting on; "We fear God, and push," he said. With urbane wit and humanity Dr. Hutchison pursued his analogy and suggested that both Jews and Scots were really strangers in England and should always remember that they were the guests of a kindly and tolerant people.

The toast of "The London Jewish Hospital Medical Society and its President" was proposed in a brief and sincere speech by Mr. R. Scott Stevenson. After words of praise for the President of the Society, Professor Cohen, and for Mr. Arnold Sorby, he said that in his opinion too great limitations should not be placed upon the number of Jewish doctors to be admitted into this country from Central Europe. Replying on behalf of the Society, Mr. Arnold Sorby said that the present persecution of the Jews was not a specifically Jewish problem, but had its wider aspect—it was essentially an attack upon the dignity of human life.

Later on in the evening Professor Samson Wright, after giving details of the plight of Jewish refugees and of the tragedy of the Jewish population in Germany at the present time, said that the Jewish population in this country had a special obligation and duty to perform. It was only right that the rest of the community should expect the Jews to do everything they could to help it to look after members of their own race. There were, he reckoned, about a thousand Jewish doctors and dentists in this country, and if they would each sign a covenant to subscribe £5 a year for seven years they would be able to guarantee the sum of £50,000, taking into account the Government refund of income tax. An anonymous donor had already given £750, and he hoped that others, too, would be able to contribute sums in excess of the minimum specified. He felt it must be their responsibility that food and lodging should be provided for those Jewish doctors recently allowed to enter the country, with permission eventually to practise medicine after studying here. He was confident that every Jewish doctor and dentist in the country would readily respond to this appeal. In connexion with the committee which had recently conferred with the Home Office on this question he would like to thank Dr. Robert Hutchison for his sympathy and interest, and also Dr. G. C. Anderson, Secretary of the British Medical Association.

The Hearing Aid Manufacturers Association has been formed with headquarters at 30A, George Street, Hanover Square, London, W.1. The founder members are Allen and Hanburys Ltd., Amplivox Ltd., John Bell and Croyden Ltd., Peto Scott Electrical Instruments Ltd., Radio-Aid, Ltd., and Aural Appliances Ltd. (Sonotone). One of the chief aims of the new association will be co-operative effort to educate and advise the deaf to buy hearing aids from reliable manufacturers only, working in closest contact with the medical profession.

Reports of Societies

INVESTIGATION OF MALIGNANT DISEASE

At a meeting of the Medical Society of London on December 12, with Dr. C. E. LAKIN in the chair, a discussion took place on the investigation of cases of malignant disease of the breast and urinary bladder.

Carcinoma of the Breast

Mr. ERIC PEARCE GOULD said that from the point of view of treatment the preliminary investigation of breast cases was to-day a matter of greatest importance. Treatment was no longer wrapped up in the single question: Can surgery remove all the apparent disease? X rays and radium, either or both plus surgery, were now alternative lines of treatment. Radical operation for carcinoma of the breast was only the proper procedure if in a particular case the operation could be truly radical—that is, include a wide margin of apparently healthy tissue in every direction; and surgery of this kind, when there were possible alternatives, was only justifiable if the risk of the operation to life was negligible. The truly radical operation was out of the question if the growth, however small, was at the extreme inner or upper limit of the breast. If gland tissue was minimal, as in the case of the male, radical operation was impossible. The extent of skin involvement would determine the total area of skin that must be sacrificed, and if this were excessive it might itself deter some surgeons. The distressing features attending ulceration of the growth had made operative removal as a palliative measure recommended, but to-day radiotherapy should be given a chance before this was undertaken.

The points to be observed with regard to glandular involvement were not only the site of the glands but their number, size, and fixity. If an enlarged gland was found in the opposite axilla it was always worth while removing it for histological examination before concluding that carcinoma had spread so far. With regard to the heart, he had long held that any woman capable of leading an ordinary life was fit for mastectomy whatever the size, sound, or rhythm of the heart might be. The same was true of patients who were chronic asthmatics and/or emphysematous, but raised blood pressure was a contraindication. Diabetes to-day involved no particular operative risk if sufficient time were allowed beforehand for stabilization. No woman welcomed the mutilation of mastectomy, but most of them accepted it when advised by a practitioner they knew and a surgeon they trusted; in private practice he met from time to time a patient who was genuinely terrified of the operation or hopelessly neurotic, and he offered her in the first instance an alternative treatment.

Tumours of the Bladder

Dr. J. SWIFT JOLY said that from two-thirds to three-fourths of primary tumours of the bladder were papillary, and varied greatly in their degree of malignancy. At one end of the scale was the benign papilloma. The next type was the malignant papilloma—a contradiction in terms and yet a convenient expression, for the tumour was essentially papillary, and usually could not be distinguished by the naked eye from a benign papilloma, but in certain portions the villi might be noticed as shorter and thicker than elsewhere, due to alteration in the epithelium. Those who held that proliferation was the first sign of malignancy would have no hesitation in excising, while those who considered that infiltration was the true criterion were forced to look upon them as pre-malignant growths. Owing to the absence of malignant infiltration they were amenable to cystoscopic diathermy.

Every patient suffering from an intermittent haematuria should be cystoscoped as soon as possible. If the early

symptoms resembled those of cystitis it was usual to find that the patient was not sent up for examination until a long treatment with urinary antiseptics had proved unsuccessful and valuable time had been lost. The position of the tumour was important and materially influenced the choice of operative treatment. Most of these growths arose from the posterior lateral wall, a considerable number from the lateral wall well above the ureteric orifice. For resection of the growth to be possible there must always be a healthy area at least half an inch wide between the growth and the internal meatus. If the tumour was so placed that resection with a sufficient margin of healthy tissue would involve both ureteric orifices a partial cystectomy should not be attempted. Involvement of one ureteric orifice was not a contraindication to a partial cystectomy, nor did it add much to the difficulty of the operation, though it increased the risk because it opened the door to an ascending infection.

Descending pyelography gave a great deal of information as to the conditions in the upper urinary tract and the state of the bladder. Failure to secrete uroselectan or a similar dye must not be taken as an indication that the kidney was permanently functionless. As for the results of operation, radium implantation had proved most disappointing; he had not had one successful case. Partial cystectomy was suitable for cases in which there was a circumscribed carcinoma which did not encroach on the internal meatus or both ureteric orifices. With total cystectomy the great difficulty was the disposal of the ureters; until some safe procedure was devised in this respect the operation could never become popular.

General Discussion

Professor G. GREY TURNER stressed the need for general clinical examination in all cases of malignant disease. He had been impressed by the writings of Halsted, who was accustomed to spend an hour in the ordinary examination of a case of malignant disease of the breast. During recent years he had been interested in the great frequency with which there were secondary deposits in bones in patients who looked and felt well. He had been a little surprised to hear Mr. Gould say that the patient with high blood pressure was a bad patient for surgery. In his experience such patients seemed to get over the operation fairly well. It was a mistake to operate during the immediate premenstrual period, when haemorrhage was sometimes alarming. On types of patients in general, he was never afraid of the small shrivelled-up elderly woman, but he was rather afraid of the florid woman with a tendency to stoutness.

Mr. ZACHARY COPE mentioned cases in which carcinoma of the rectum had followed a year or two after the breast had been removed for carcinoma. A routine x-ray examination should be made in every patient whose breast was to be removed. Some patients had early deposits in the lungs which x rays would reveal. He agreed that deposits in bone might not be seen, though they might be suspected; examination of the blood would give some information as to early secondary deposits in the bones.

Mr. L. E. C. NORBURY also commented upon the simultaneous appearance of carcinoma in the breast and in the rectum. He mentioned a case of simultaneous carcinoma of both breasts, which were removed within three weeks of one another, followed by treatment with deep x rays; the patient was still alive ten years afterwards. Sir JAMES WALTON said that he was one of those people who believed that most of the younger surgeons of to-day would see the time when no case of carcinoma of the breast was operated on at all. They would all be treated by deep x rays, or some agent of that kind. Mr. E. W. RICHES considered that in carcinoma of the bladder more use should be made as a diagnostic measure of trial cystodiathermy. In cases in which it was doubtful whether a malignant growth or a papilloma was concerned a prolonged cystodiathermy would solve the problem. It was surprising how many of them responded, showing that they were of the type that was at any rate not

infiltrating. The so-called ordinary examination could be rather overdone, especially in cases of haematuria. The essential examination was by the cystoscope.

Dr. C. E. LAKIN, from the chair, said that surely a patient having Bright's disease with haematuria should not be subjected to cystoscopy. He would have said that cystoscopy was a special examination to be made after a general examination had failed to elicit the cause. So many of these cases were now going straight to specialists for special examinations, and many people were being subjected to the most disagreeable forms of examination which in the long run were unnecessary. Mr. RICHES retorted that the surgeon also saw cases which had been treated as Bright's disease but were in fact cases of carcinoma of the bladder. He stressed examination with the cystoscope not more for the value of its positive than for the value of its negative findings. Properly carried out, cystoscopy was no more disagreeable than a barium enema.

ADDISON'S DISEASE: RECENT DEVELOPMENTS IN TREATMENT

At the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on December 13, with Dr. E. C. WARNER in the chair, recent developments in the treatment of Addison's disease were discussed.

Dr. S. LEVY SIMPSON said that the first real advance was the preparation in 1930 by Swingle and Pfiffner of a potent extract of the adrenal cortex. For a severe case of Addison's disease from 5 to 20 c.cm. was given daily intramuscularly. The next advance was made in 1935 by Loeb and his co-workers, who showed the value of sodium chloride and other sodium salts, given by mouth, in doses of 12 grammes daily, in permitting a reduction of the dose of cortical extract. Some relatively mild cases were maintained in health by salt only. The serum potassium was found to be raised in this disorder, and workers at the Mayo Clinic advocated a low potassium diet, but in the speaker's experience this had not been worth the enormous trouble of preparation. None of the various methods of extracting the active principle of the adrenal cortex in solvents such as glycerin which permitted its action when given by mouth had so far had material success. Adsorption on charcoal had proved efficacious in animals, and he had seen some degree of benefit in man from this therapy. No major advance seemed likely until the essential constituent of the adrenal cortex had been isolated and synthesized. The isolation had been effected by Steiger and Reichstein of Zürich in 1937, and the preparation had been named corticosterone (cortin), but it had not yet been synthesized, though a closely related compound, desoxycorticosterone, had been synthesized from stigmasterol. He had found 5 mg. of this substance in 1 c.cm. to be equivalent to 10 c.cm. of cortical extract in treating Addison's disease. It was an oily solution and was injected intramuscularly.

Dr. Simpson also reported on the effect of subcutaneous implantation of this substance. Its anabolic action reminded him of that of testosterone propionate, and his previous experience of such procedures related to a castrated male in whom he had implanted tablets of testosterone, the effect of which remained at a maximum for about two and a half months. In connexion with Addison's disease he had tried the effect of inserting four tablets of 50 mg. of desoxycorticosterone underneath the skin under local anaesthesia. Over a period of a few weeks the absorption appeared to be as effective as when the material was given by daily intramuscular doses. In one patient in whom 5 mg. of the preparation twice daily had proved to be a substitute for 20 c.cm. of cortin he implanted tablets in the way described, and she had carried on quite well. He also reported good results in three other cases, but he was convinced that this synthetic hormone, desoxycorticosterone acetate, was not the only essential principle in the protein cortical extract.

Maintenance Dose with Cortical Extract

Dr. J. F. WILKINSON said that the doses of cortical extracts or synthetic desoxycorticosterone might be considerably reduced by the use of subsidiary treatments, particularly salt or salt mixtures, and by potassium-free diets. He described some work carried out under the auspices of the Therapeutic Trials Committee of the Medical Research Council. In a group of thirteen patients with Addison's disease who had been treated with cortical extracts four had died, two of these being found to be grossly tuberculous. The nine surviving patients had been on cortical extract for varying periods, in one case for fifty-six months. All were typical cases with the classical symptoms. One of them had had in the course of fourteen months as much as 6 litres of cortical extract, and his final maintenance dose was 20 c.cm. daily. Several of the patients had now been put off cortin, but they were all having salt. Cortical extracts were obviously of great value in maintaining many of these patients, but they were so costly that there was a tendency among doctors to reduce the amount given in treatment to dangerous levels.

Desoxycorticosterone had been given to four patients in his series, three of whom were well at the present time; one had died. This last showed at necropsy the largest tuberculous suprarenals he had ever seen. The best results with this preparation were apparently in patients free from tuberculous foci. The amounts given, intramuscularly, had been from 5 to 18 mg. daily; no reactions either local or general had been observed. Two patients had been put on to maintenance doses of 5 mg. weekly, and one on to this dose twice weekly. Cortical extracts might be required in initial daily doses of (40 to 100) c.cm., and some patients might need a daily maintenance dose of 20 to 30 c.cm., while others required less than 2.5 c.cm. monthly, particularly when taking increased salt. Desoxycorticosterone appeared to be a complete substitute for the natural cortical extracts, but until a larger number of cases had been compared it was difficult to assess the exact clinical equivalence. There was no doubt that salt had a place in the treatment of Addison's disease in severe or moderately severe cases, but he did not think that salt by itself was of any value at all. There were patients who could not tolerate salt in any dosage. He also exhibited the low potassium diet sheets which were recommended. The diet was deficient in most mineral salts. The patients were put on to the best white bread and cereals, but their intake of meat and vegetables had to be restricted. They were given soups, sauces, meat extracts, and chocolate.

Anaphylaxis after Intravenous Administration

Dr. H. P. HINSWORTH said that by means of cortin and salt cases of Addison's disease could be controlled and a fair measure of well-being imparted. He was convinced of the deleterious effects of a high potassium intake, and while it might not be advisable to give a patient a low potassium diet it was certainly necessary to ensure that he did not take a high one. He had found cortical extract to be an extremely reliable preparation, but one fatal case of anaphylaxis had occurred in his experience. This was a patient who first came under treatment in the summer of 1936. She was eventually sent out and ordered 5 c.cm. of cortin daily. About a fortnight before Christmas she received her last injection of cortin. She then contracted influenza, but she was no worse than any other influenza case. One morning, however, she was found unconscious. A doctor gave her 5 c.cm. of another preparation of which the speaker was unaware, and she was sent to hospital, where as much as 80 c.cm. of cortin was given intravenously. She regained complete consciousness, but a few hours later she began to breathe with difficulty and died the following morning. At post-mortem the lungs, instead of collapsing, ballooned out over the cut edges of the ribs. The cause of the disease was atrophy of the suprarenals.

He had tried desoxycorticosterone acetate (Ciba) in two cases of Addison's disease. The blood chemistry was kept within normal limits throughout the period of observation, but in both cases, after an initial period of increased well-being, clinical relapse occurred. There were two possibilities: (1) that the preparation was toxic over a long period; (2) that it did not contain all the necessary active principles of the cortex required to treat Addison's disease. While cortin was both reliable and practically free from danger in the treatment of Addison's disease, desoxycorticosterone must be said to be still in the experimental stage.

BRONCHIECTASIS

A meeting of the North-Western Tuberculosis Society was held in Manchester, with the president, Dr. G. JESSEL, in the chair. Dr. W. BROCKBANK and Mr. A. GRAHAM BRYCE read papers on bronchiectasis from the points of view of the physician and the surgeon respectively.

Dr. Brockbank said that in bronchiectasis there was dilatation of the bronchi or bronchioles, which might or might not become secondarily infected. Among the causes of this condition he mentioned congenital narrowing of the bronchi, pressure from a growth or aneurysm, intrabronchial tumours or foreign bodies, and most of the inflammatory diseases of the lungs and air passages. It was possible that inflammatory changes so weakened the bronchial walls that they bulged on coughing, the bronchial musculature lost its tone, and the bronchi became dilated. The elastic fibres and, later, the cartilage were destroyed and replaced by fibrous scar tissue, which might cause a partial obstruction damming back the expectoration in the alveoli and causing a softening of the walls. There was also a pull exerted on the softened walls by the fibrous tissue. This theory did not account for the dry variety of bronchiectasis in which there was little cough or expectoration, rarely any evidence of bronchitis, and very little fibrosis. In a recent paper Lander and Davidson had recorded their conviction that massive collapse of the lung was a necessary and an invariable antecedent to the bronchial dilatation. Whatever might be the cause or whatever the type of bronchiectasis it was essential to realize that the dilations were nearly always surrounded by fibrous tissue, that the cavities were themselves lined with epithelium, and that it was almost always the lower lobes which were affected. These facts influenced the whole course of treatment.

Signs and Symptoms

Dr. Brockbank described in detail the physical signs and symptoms of advanced bronchiectasis, and said that the copious foul-smelling yellow sputum was characteristic of the advanced stage of the disease only. In the early stages of the disease the signs and symptoms were slight. In the dry type of bronchiectasis there was cough, with not more than half an ounce of sputum—which was not typical bronchiectatic sputum—and haemoptysis, which might be repeated and profuse. The constitutional symptoms were mild or absent and the physical signs indefinite. Other types might be masked by contributory diseases—chronic bronchitis, asthma, pulmonary fibrosis, tumour, or emphysema. The bronchitic type was the most common. Here physical signs, apart from rhonchi and rales, were generally absent, and the diagnosis was only suspected from the clubbing of the fingers, the unsatisfactory response to treatment, and, radiologically, from fibrosis at the bases of the lungs.

Bronchiectasis was usually bilateral and the treatment was usually medical, for the surgeon was concerned only with unilateral disease. In dry bronchiectasis only a simple tolu and squill cough mixture and breathing exercises were needed. Where the sputum was fairly copious, creosote, in capsules, in the form of an inhalation by means of a Yeo inhaler, or in a creosote chamber, was

useful. Some preferred the use of garlic instead of creosote. Menthol and guaiacol, injected intratracheally by means of a special syringe, was also advocated. Postural drainage was valuable, but must be kept up indefinitely. It was necessary to determine the exact area diseased so that the posture adopted should drain the sputum into the main bronchus, from where it could be expectorated. He considered the types suitable for operation were: (1) cases with unilateral disease; (2) cases with foul-smelling sputum; (3) cases with recurrent attacks of pneumonia; (4) cases in which the continual coughing of sputum was an embarrassment; and (5) cases of dry bronchiectasis with repeated haemoptyses. In the vast majority of cases of bronchiectasis artificial pneumothorax had proved a failure.

Surgical Treatment

Mr. Graham Bryce referred to Carl Hedblom's use of phrenic evulsion in cases of delayed resolution or early pulmonary fibrosis after bronchopneumonia which brought about symptomatic cures; the patients did not relapse and lipiodol failed to show bronchial dilatation. Alexander, too, had had good results from the phrenic crush operation in cases of suppurative pneumonia before the stage of abscess formation or of chronic bronchiectasis. Artificial pneumothorax and phrenic evulsion were on the whole unsatisfactory. Phrenic evulsion had a special disadvantage in that it interfered with the efficiency of the cough mechanism. Thoracoplasty had had a thorough trial and had now been almost entirely abandoned in the treatment of non-tuberculous bronchiectasis. He had little to add to what Dr. Brockbank had said about postural drainage, and he agreed that it was a method of the greatest importance by itself or in the pre- and post-operative management of cases treated surgically. He regarded bronchoscopic aspiration for bronchiectasis as largely a waste of time, although he advocated diagnostic bronchoscopy in every case.

Pneumonectomy and Lobectomy

Bronchiectasis did not respond to treatment by external drainage as it was difficult to drain more than a few of the affected bronchi. Thoracic surgeons nowadays considered that almost the only worth-while method of treating the disease was by ablation. Defining the term "pneumonectomy" he said it meant, rather paradoxically, either excision of part of a lobe or the extirpation of an entire lung. Cautery pneumonectomy had almost entirely given place to lobectomy or total pneumonectomy, but he thought it could be undertaken in selected cases more often than it was, although it left more deformity of the chest wall than either of the more radical procedures. There was much discussion concerning the relative merits of the one-stage and two-stage methods of lobectomy. He described the one-stage method of Brunn and Shennstone and also the two-stage or Alexander's method. There was no doubt that the one-stage technique was gaining ground. In patients awaiting lobectomy it was important to make specific inquiry regarding the possibility of an inhaled foreign body. In the medical examination attention must be paid to the heart muscle, the vital capacity, and the possibility of amyloid disease. The blood must be grouped and the nasal sinuses x-rayed. The teeth should have any necessary treatment. Tuberculosis must be excluded. It was important that the patient should have postural drainage for four to six weeks, and it was advisable to begin breathing exercises before the operation.

The exact anatomical distribution of the disease was extremely important to the surgeon, and it was necessary to make bronchograms of each lung separately. An apparently excellent postero-anterior bronchogram was often found to be inadequate when a lateral film was made. In children, who required a general anaesthetic for

every x-ray examination with lipiodol, it was often possible to get an accurate localization of the disease from a single picture. Where all the lobes of one side were found to be affected the introduction of a little lipiodol into the base of the other lung might demonstrate that the case was beyond the reach of surgery and thus save the patient attending for another bronchogram. For bronchography he used a catheter introduced orally through a laryngoscope or, in some cases, Singer's method. Blood transfusion or oxygen-tent therapy was often advisable in the immediate post-operative period, although he did not use them as a routine. A bronchial fistula and a localized empyema occurred in practically every case. The patient was usually in hospital for two months after his operation.

Results of Operation

Professor Sauerbruch's recent survey of 387 lobectomies revealed a mortality which varied from 13 per cent. to 24 per cent., the average being 21 per cent. Churchill of Boston had a series of forty lobectomies for bronchiectasis with a mortality of 5 per cent. Mr. Graham Bryce's own series comprised twenty-eight operations on twenty-seven patients. The immediate mortality rate calculated on five patients who died within two months of the operation was 14.3 per cent. Two patients died later, one five months after the operation and one two years after; this gave a total mortality of 25 per cent. Of the remaining twenty patients four were still under treatment, though in the convalescent stage. Of sixteen others, in thirteen the result had been very satisfactory and the patients were able to lead practically normal lives. In none of these was the sputum offensive, even where it had been before the operation. The other three patients were all in good general health although they had some degree of residual bronchiectasis. Mr. Graham Bryce concluded his remarks with the warning that thoracic surgery was a very specialized field in which experience was dearly bought, but in his opinion the surgical treatment of bronchiectasis was well worth while.

PATHOLOGY OF CHRONIC AORTIC VALVULAR DISEASE

At a pathological meeting of the Liverpool Medical Institution on December 1, with the president, Dr. E. GILBERT BARK, in the chair, Dr. R. Y. DAWBARN read a paper on the pathology of chronic aortic valvular disease.

Dr. Dawbarn said that there were three common chronic diseases of the aortic valve—syphilis, rheumatism, and Mönckeberg's calcific degeneration. In many cases the macroscopical features sufficed to distinguish these conditions, but difficulty was most likely to occur where much calcification had followed an old rheumatic process, and where the calcific degeneration of Mönckeberg was accompanied by marked fibrosis. In such cases microscopical examination might be very helpful, and it was advisable to stain the sections by some method which showed the elastic fibres. In cases of old rheumatic disease the cusps were opaque and thick, especially along the free border, and some, or all, of the following microscopical changes could usually be found:

1. Thickening of the ventricular layer of the cusp with reduplication of the elastic lamina, especially in the sub-aortic angle.
2. Vascularization of the cusps and ring with capillaries and muscular arterioles.
3. Scarring of the ring with increase of elastic fibres.
4. Calcification in either the ventricular or aortic layer.
5. Thickening of the subendothelial tissue in the pocket.

Rheumatism in early life might lead to a bicuspid deformity of the aortic valve; Louis Gros considered that

most cases of this condition, discovered in adults, had a rheumatic basis. Mönckeberg's calcific degeneration was a disease mainly of the fibrous aortic layer of the cusp characterized first by the deposit of lipoids and then by calcification. Large calcified, craggy masses might be formed in the cusps and project mainly into the sinuses of Valsalva. The ventricular layer of the cusp was not thickened, as in rheumatism, but was usually normal, or else thinned out by reason of the stretching and distortion caused by the calcareous masses.

In the discussion which followed Dr. W. S. SUTTON and Dr. A. M. ABRAHAMSON took part. Pathological specimens were then shown by Mr. HUGH REID, Dr. G. D. OWEN, and Dr. RONALD ELLIS.

Local News

ENGLAND AND WALES

Westminster Hospital Medical School

The annual dinner of past and present students of Westminster Hospital Medical School was held at the Trocadero on December 13, with the dean, Dr. Adolphe Abrahams, in the chair. Proposing the toast of "The School," Dr. Abrahams said that the Westminster was now in the greatest year of its history, and those present were paying honour to the school and to all generous benefactors who had helped to build it. The president (Lord Wigram), the chairman (Mr. B. D. F. Doeker), and the secretary (Mr. Charles M. Power) were with them that evening to prove the close bond between hospital and school. When they dined together once again in ten months' time the new Westminster would be completed. Dr. Abrahams paid affectionate tribute to Mr. E. Rock Carling, the senior surgeon, without whom it was difficult to believe that there would ever have been a new Westminster. After some witty suggestions for slogans for each department, so that the hospital might "put itself across to the public," he called upon a distinguished old student, Mr. C. Price Thomas, and the honorary secretary of the Students' Union, Mr. G. Martin Jones, to reply to the toast. Mr. Rock Carling proposed "The New Hospital" and spoke of the adaptation of its structure to function and of the old fine spirit of the place which would carry on into the new phase. He said that in several ways the Westminster had given a lead to other hospitals in respect of construction and equipment. Mr. Doeker, replying to the toast, declared that the new building would be one of the finest hospitals of its kind in the country. It was being erected with the blessing of the Ministry of Health, the L.C.C., the Middlesex County Council, and the Westminster City Council. In pursuit of its ideal of co-operation, general practitioners would be encouraged to visit their patients in the hospital, to act as clinical assistants, and to attend short postgraduate courses. The hospital would provide 400 beds (350 of them available for teaching purposes), and it was safe to assume that patients would be admitted to the new building in May next. The senior staff had been most helpful and unselfish in tackling the problem of allocation of beds between the various departments. The health of the guests was submitted in happy phrases by Sir Stanley Woodwork, who welcomed many old friends of the hospital and school, and in particular Dr. Robert Hutchison, P.R.C.P., Professor J. A. Ryle, Professor G. E. Gask, Dr. K. J. Franklin, and the Editors of the *Lancet* and the *British Medical Journal*. Lord Macmillan, in acknowledging the toast, said that London University was proud of its medical schools and of their work in promoting the greatest of the sciences. The last toast, very warmly received, was that of "The Chairman," proposed by Mr. Arthur Evans.

Tuberculosis in Lancashire

The report of the Central Tuberculosis Officer (Dr. G. Lissart Cox) for the year 1937 shows that the death rate from pulmonary tuberculosis in the County of Lancashire has remained the same as in the previous three years—0.46 per 1,000 of the population—and there has been an increase of sixty over 1936 in the number of new cases of pulmonary tuberculosis reported. Similarly in regard to non-pulmonary tuberculosis, the death rate—0.10 per 1,000 of the population—is the same as in 1935 and 1936, and the number of new cases reported shows an increase of twenty-nine over the previous year. Bearing on the importance of early diagnosis in the campaign against tuberculosis, Dr. Lissart Cox carried out an investigation, and found that between 1920 and 1937 the duration of symptoms from their onset to the date the patient consulted his medical attendant had declined by 61 per cent. to 2.9 months for negative-sputum cases, and by 48 per cent. to 4.2 months for positive-sputum cases. The period the patients were kept under observation by their medical attendants showed similarly a decline of 40 per cent. to 3.2 months for negative-sputum cases, and of 27 per cent. to 3.5 months for positive-sputum cases. Dr. Cox comments that "the reductions are welcome, but there is still much room for further improvement both on the part of the patient and the medical attendant." Co-operation with the medical practitioners, together with the medical officers and sanitary inspectors of county district councils, is shown in the fact that no less than 92 per cent. of new cases (excluding contacts) were sent *before notification* to the tuberculosis officers for an opinion as to diagnosis and treatment. The examination of contacts remains unsatisfactory—only 45 new child contacts and 51 new adult contacts were examined per 100 deaths from tuberculosis. The respective figures for England and Wales are 95 and 82, and even these figures are generally admitted as being far too low. Finally, attention may be drawn to the liberal staffing of the dispensaries in Lancashire: it compares very favourably with other counties in England. The report contains a very clear and well illustrated account of tomography by Dr. F. S. C. Bradbury, which deserves wide publicity.

Empire Rheumatism Council

The Empire Rheumatism Council began its work in October, 1936, and had as one of its avowed objects the education of the public with regard to rheumatic diseases. Its educational programme has been continued with success, despite the preoccupation of the British people in recent months with gas masks which do exist and bomb-proof shelters which do not. With the co-operation of the Press the man in the street is gradually being made to realize that rheumatism is a disorder affecting not only the health but also the economic well-being of the community. An affiliated Council is undertaking the same sort of educational work in Canada, and it seems likely that an Australian Rheumatism Council will come into being within the next few months. The volume of work undertaken by the Scientific Advisory Committee of the Council has been such that it has become necessary to establish three subcommittees—bacteriological, chemical, and physical—for the preliminary examination of suggestions for treatment. Dr. C. A. Green has been appointed to take direct charge of an investigation into the causes and the best means of prevention and treatment of rheumatic disease in the training establishments of the Royal Navy. The Medical Research Council has co-operated in the important task of allotting research grants and fellowships, and work is in progress on a variety of problems, the most important of which is perhaps that of preparing a report on a system of treatment which might be economically applicable on a national scale. It is hoped that this particular report will be completed in the early part of the New Year. New treatment centres

have been established in connexion with different hospitals during the past year, but they are still too few. It is probably true to say that even now specialized treatment is available in England and Wales for less than 10 per cent. of the million or more adult cases of rheumatic disease and for less than 25 per cent. of about half a million juvenile patients. These disturbing figures were given by Lord Horder, the chairman of the Empire Rheumatism Council, on Monday last in the course of his second annual report. Even so, the situation is better than it was twelve months ago, thanks largely to the efforts of the Council. Lord Horder also referred to the recent Cancer Bill and went on, perhaps prophetically, to hope 'that "with the growth of knowledge of the tragic degree of human suffering and economic loss caused by rheumatism this will also shortly be fully recognized as a national problem."

Manchester Hospitals Advisory Board

The third annual report of the Manchester Joint Hospitals Advisory Board reveals continued progress in co-operation between voluntary and municipal hospitals in the Manchester area. A scheme for co-ordinating the treatment of fractures, which follows the principles laid down in the British Medical Association's report, has been agreed upon; the existing fracture services will be grouped in northern, central, and southern areas and a free interchange of patients between the hospitals within each group should make for greater efficiency and should steadily diminish the overlapping and duplication of services which seemed inevitable only a few years ago. Thoracic surgery in Manchester is to be concentrated in two units with one surgeon in charge of both; that at the Royal Infirmary will deal with all non-tuberculous cases, that at Withington Hospital with all tuberculous cases. The question of establishing a central hearing-aid clinic is being considered and work on other problems of co-ordination continues. In Manchester, at least, it would seem that Section 13 of the Local Government Act of 1929, which has since been repealed and re-enacted as Section 182 of the Public Health Act, 1936, is being implemented as fully as it possibly can be.

Food and Drugs Act, 1938

The Minister of Health has issued a circular to all local authorities and public analysts on the new Food and Drugs Act passed last July. The Act does not come into force until next October, but it should receive early study and attention, for it represents a very great simplification of the existing Food and Drugs Law, a process which has involved many minor amendments. The opportunity has also been taken to introduce into the general law provisions which have up to now only been included in Local Acts. The existing legislation dates back many years—some of it to the sixteenth century—and modern methods of food sophistication and advertising have revealed loopholes which it is hoped the new Act will effectively close. Among the new provisions which will become enforceable in October next are the registration by local authorities of premises used for the sale or manufacture of ice-cream and the preparation or manufacture of sausages or preserved food; ice-cream vendors must have their names and addresses on stalls, carts, barrows, etc., and this requirement may be extended in any district to all or any other foods by the local authority. Slaughterhouses and knacker's yards will all in future be licensed for limited periods only, and this includes those now known as registered slaughterhouses and those licensed without limitation of time. It will be an offence to dispose of meat from a knacker's yard for human consumption, and local authorities may require records to be kept of animals and carcasses in such yards. In addition new requirements are laid down as regards rooms, yards, etc., in which food is sold or prepared for sale. The Act largely follows a draft

Bill prepared by a departmental committee and explained by them in their report published in December, 1937 (Cmd. 5628; 1s.). This report very fully explains the amendments in the law, and the circular now issued merely elaborates certain points. The circular is numbered 1755 and may be obtained from the Stationery Office, price 2d.

The L.C.C. and the Cancer Bill

In reporting to the London County Council on the Cancer Bill, which received a second reading in the House of Commons last week, Mr. Somerville Hastings and Mr. Charles Latham, chairmen respectively of the Hospitals and Medical Services and the Finance Committees of the Council, state that substantial facilities already exist for the diagnosis and treatment of cancer in London, and while it is recognized that there is a need in various parts of the country for the provision of further facilities, it is not clear, so far as London is concerned, that there is any need for the imposition of a statutory duty upon the L.C.C. to ensure that arrangements for the diagnosis and treatment of cancer shall be adequate. The Council treats cancer patients in all its twenty-seven "acute" general hospitals, and there are special units for deep x-ray and radium therapy at Lambeth and Hammersmith Hospitals. Many voluntary hospitals treat cancer patients, and some have spent considerable sums on radium and x-ray apparatus. The total number of admissions of cancer patients to the Council's hospitals in 1937 bordered on 7,000. At a conference between the Minister of Health and representatives of the L.C.C. and others it was understood that the inclusion of voluntary hospitals as circumstances may render desirable in schemes prepared by local authorities may embrace not only the provision of treatment but also the provision of diagnostic centres. The choice of hospitals, both municipal and voluntary, for inclusion in schemes will naturally depend upon the needs of the area to be served and upon the service which the hospitals are equipped to render.

At the interview with the Minister the Council's representatives submitted that Exchequer grants towards the expenditure of voluntary hospitals in London should be made direct to such hospitals without supplement from the rates and without prejudice to the Council's responsibility for the preparation of a scheme for cancer in the metropolis. The Minister, however, stated that he thought the scheme would work more smoothly and efficiently if the control were in the hands of the local authority, and that it would be better for the authority to pay the grant due under the scheme to the voluntary hospitals. Those speaking for the Council do not share this view, and hold that grants from public funds to voluntary hospitals for cancer treatment and facilities should be paid direct by the Minister. It is also considered that, as the additions to the expenditure of local authorities by the imposition of further statutory duties have already heavily intensified the Council's financial burdens, the proposal to scale down the grant in respect of the new cancer service below a minimum of 50 per cent. to any authority should be resisted. The Minister's suggestion is that as the existing facilities for dealing with cancer in the areas of the "richer" authorities are so much better than in the areas of the "poorer," the cost to the former would be comparatively small, and therefore there is justification for their percentage of Exchequer grant being scaled down.

It is anticipated that the unit cost in London will be materially higher than the country average, having regard to the higher standard of costs to which the cancer service in London will unavoidably be subject. The L.C.C. maintains that the object of control over the expenditure of local authorities could equally well be secured by substituting for the average for the whole country an approved unit for regions in which special local factors would receive proper recognition, and the Minister has intimated that he is prepared to consider this point.

SCOTLAND

The R.C.P. Laboratory at Edinburgh

The annual report of the Laboratory of the Royal College of Physicians of Edinburgh records the resignation of its Curator, Sir Robert Philip, after nearly thirty years of active official association with the laboratory. Sir Robert had held the appointment of Curator for the past fourteen years. During the year under review thirteen papers were published by workers in the research department. Further investigation of anti-rabies treatment statistics includes a study of the figures from the Union of Soviet Socialist Republics. It appears that during the years 1927 to 1934, 343,149 persons were treated in Russia, and 584 (0.17 per cent.) of them contracted rabies. The most striking feature of these statistics is a steady decline in the number of people presenting themselves for treatment, attributable to "an abrupt diminution of rabies in animals in the U.S.S.R." Among other researches are studies of the mode of action of cod-liver oil and certain other oils in the treatment of wounds. Experiments *in vitro* have shown that cod-liver oil, both in the presence and in the absence of a nutrient medium, possesses a strong bactericidal action, which is markedly increased by previous irradiation of the oil with ultra-violet light. Of other oils investigated, only linseed oil proved to be more potent than cod-liver oil, but for various physical reasons this substance is contraindicated as a means of treatment. In the field of parasitology trichomonas infections have been studied, and it has been demonstrated that *Trichomonas vaginalis* and *Trichomonas intestinalis* differ from one another in morphological and cultural character. Vaginal infection with this parasite appears to be far more common than is generally supposed. Conditions predisposing to infection, and the part played by the parasite in causing sterility and other pathological changes in the genital tract, are under investigation.

The Blind in Scotland

At the opening of an extension to the Royal Blind Asylum, Edinburgh, on December 9, Mr. W. J. Anstruther Gray, Parliamentary Secretary to the Secretary of State for Scotland, said that this institution had been founded by Dr. Johnson of Leith in 1793, and the school had been added by James Gall in 1835. Since the Blind Persons Act of 1920 expenditure in Scotland on behalf of the blind had risen from £80,000 to £300,000, and 9,000 blind people were provided for. The number of blind children had greatly decreased, and the increase in the total number of the blind was due to longer life. Mr. James Adshad, chairman of the Board, said that estimates for the extension amounted to £20,000, of which education authorities throughout Scotland who sent children to the school were expected to provide three-fourths, leaving about £5,000 to be found by the institution itself.

Treatment of Venereal Diseases

The current annual report of the City and Royal Burgh of Edinburgh Venereal Diseases Scheme opens with a masterly synopsis of the advances in treatment during the last twenty-five years. It is recalled that it was the Edinburgh Corporation which, in 1928, promoted and presented to Parliament a Bill designed to secure compulsory powers for the examination and treatment of known or suspected cases of venereal disease. The Bill, however, was not passed, for the enforcement of such legislation would present considerable difficulties. The employment of sulphamidamide and its derivatives produced highly satisfactory results in the treatment of gonorrhoea during the year under review. An allied preparation—uleron or disethyl—was also given extensive clinical trials. The clinical officer states that in the majority of cases the effect of these new drugs has been amazingly rapid, resulting in the disappearance not only of the

signs and symptoms of the disease but also of the causative organisms within a few days. The response, however, was not satisfactory in every case, and to this extent their action may be described as inconstant and "capricious." The report records a considerable increase in the number of new patients. This is chiefly accounted for by a larger number of cases of non-specific venereal disease, syphilis and gonorrhoea showing a slight diminution. Analysis of new cases gives the following figures, those of the previous year being shown in parentheses: Total number 2,860 (2,540); syphilis 686 (695); gonorrhoea 1,256 (1,280); chaneroid 35 (27); non-specific venereal disease 883 (538). The last named thus forms nearly one-third of the total.

Dundee Health Report

Attributable to simultaneous outbreaks of whooping-cough, influenza, and primary pneumonia during the first quarter of the year, a rise in the general death rate is recorded in the annual report for 1937 of the Public Health Department, City of Dundee. The rate for the year was 15 per thousand, compared with 14.1 in 1936 and 13.2 in 1935. These three diseases caused 406 deaths—whooping-cough 51, influenza 113, and pneumonia 242. Of the deaths from whooping-cough twenty-four occurred in infants under 1 year, and twenty-four in children aged 1 to 5. Only one death was certified as due to whooping-cough alone. The remaining cases suffered from complications, of which pneumonia was the most frequent. Among other infectious diseases scarlet fever and chicken-pox also showed an increased incidence, but with regard to measles intimations of only 312 cases were received, compared with 1,862 in 1936. The majority of the measles cases occurred in the last two months of the year under review, conforming with the usual tendency of this disease to make biennial appearance in epidemic form in the city. Of ten notifications of enteric fever, all of which were admitted to hospital, the diagnosis was accepted in eight—two typhoid and six paratyphoid B. In three of the latter cases it was thought probable that the source of infection might have been associated with the eating of periwinkles.

Correspondence

Lay Analysts at L.C.C. Mental Hospitals

SIR,—I think that you may be interested to learn the circumstances under which lay analysts are to be allowed to receive instruction in the London County Council's mental hospitals.

On November 15, 1938, a report from the St. Bernard's Hospital Committee was received by the General Purposes Subcommittee of the Mental Hospitals Committee, stating that the Director of the Institute of Psycho-Analysis had asked for permission for a small number of lay analysts to observe the technique and to study the reactions of patients at St. Bernard's Hospital, and that the medical superintendent was willing to co-operate. As this involved an important question of principle, we, the Municipal Reform Party members, asked whether before reaching a decision the Board of Medical Superintendents might be consulted, as it was a matter on which we as a lay committee were not competent to decide. This was refused. We then asked whether the question could be deferred until the committee of the British Medical Association which we understood was inquiring into the whole question of the scope of the work of lay analysts had reported. This was

also refused. The matter then came up to the Mental Hospitals Committee. Dr. Odum moved and I seconded that the matter be deferred pending a report from the committee of the B.M.A., and we were outvoted. We then asked that the matter should be reported immediately to the Council, and this was refused. Finally, under Standing Order 139A, on the request of twenty members, the matter had to be reported at once to the Council, but by rule of the Council only two five-minute speeches on each side were allowed, and therefore it was impossible fully to state our objections.

These are briefly: (1) That the matter was *sub judice* by a committee of the British Medical Association, and therefore might be prejudiced. (2) That the examination of a patient was confidential, and persons would be present who were not bound by any ethical rules and were not pledged to secrecy. (3) That before agreeing we should have full information (a) as to the scope of the work to be undertaken, and (b) as to the safeguards which were to be demanded for the protection of the public, such as whether the lay analysts would always have to work under medical supervision, etc.—I am, etc.,

London, S.E.1, Dec. 13.

BARRIE LAMBERT.

Radium Policy and Practice

SIR,—In your account of the annual report of the Radium Commission (December 10, p. 1217) you say, "it is to be hoped that the formation of a therapeutic centre [at Cambridge] in the near future will give practical expression to the ever-increasing developments of experimental radiology." As these words imply that there are no facilities for the treatment of cancer at Cambridge, and that the authorities at Addenbrooke's are adopting an obscurantist attitude, perhaps you will permit me to state the facts.

Addenbrooke's was one of the very first hospitals in the country to treat cancer by x rays, a plant having been installed in 1921 in charge of the late Dr. Shillington Scales. For some time past two plants have been in constant use. For many years candidates for the Cambridge D.M.R.E. have been taught here. The follow-up system is probably as efficient as that of many of the radium centres. As for the quality of the work, it is not for me to express an opinion. In addition to serving our own large area we have had to treat patients from one of the radium centres which, be it noted, only in the last year has provided facilities for the purpose. As regards radium the hospital possesses its own supply, purchased two years before the formation of the Commission, while in addition the gynaecological department, under Dr. Canney, uses radium lent by the Medical Research Council.

In spite of all this the Radium Commissioners, when they first established their centres, were apparently completely oblivious of the claims of Cambridge. They made no effort to investigate our achievements, difficulties, or potentialities. They merely sent us gratuitous advice to the effect that we should send our patients to Norwich. It was not until about two years ago that they made the discovery that Cambridge presented certain advantages possessed by few other towns. Since then they have lost no opportunity of proclaiming their newborn infatuation and lamenting the failure of the hospital, partly on financial grounds, to respond to their advances.

May I also dispute your statement that "treatment by high-voltage x rays is an indispensable adjunct to treatment by radium"? Although this view may still be held in certain quarters, there is a widespread and increasing

belief that the vogue for radium is declining and that more is to be expected from x rays. I think I am voicing the opinion of my colleagues when I say that in our negotiations with the Commissioners this belief at least played a part in our declining to recommend to the General Committee an offer which would have imposed too great a strain on the hospital's resources. While naturally willing to try every method we have refused to be stampeded into the view that radium is and must remain the dominant line of attack.

For my part, with all due respect, I cannot subscribe to the view that a Radium Commission which has on it no representatives of qualified radiologists is necessarily the best body to decide upon what constitutes the most efficient method of treating cancer.—I am, etc.,

Domiciliary Emergency Treatment of Eclampsia

SIR,—Dr. H. J. Thomson's note (*Journal*, December 10, p. 1204) regarding the above is interesting, but his table of results does not quite fully support his contention. During 1937 the deaths from eclampsia were *nil*, a greater number of cases (seventeen) being treated in hospital than at home (eleven). In that year, therefore, treatment in hospital would seem to have been at least as successful as domiciliary treatment.

Dr. Thomson's table gives the results of cases treated at home by the emergency team. Additional value would attach to the table if it stated how many cases of eclampsia were treated other than by the emergency team, and what the mortality was in these cases, if any. I notice that the incidence of eclampsia as treated by Dr. Thomson's service appears to have risen steadily during the years covered by his table. Does this mean that such cases are being referred to hospital in greater numbers?

I believe that the treatment of eclampsia lies in the prevention of its onset by timely termination of pregnancy rather than in the treatment of the established condition. The routine adopted in the Croydon Obstetric Service is that all cases seen at the ante-natal clinics whose diastolic blood pressure is 90 or over, with or without albuminuria, are admitted to hospital, and if the usual dietary and other treatment does not result in subsidence within about ten days the pregnancy is terminated. Cases with definite pre-eclamptic signs, especially severe headache and visual disturbances, are not allowed so long a period if there is not definite amelioration of symptoms within the first few days. As a result of the rigid observance of this rule over 300 cases of hypertension with or without albuminuria have been admitted to the Croydon County Borough Hospitals during 1937 and 1938; and no case so admitted has developed eclampsia. Two cases of established eclampsia were admitted in 1937, the pregnancy being terminated immediately in each case, with no maternal or foetal mortality.

The urea-concentration test is invaluable in these cases, and I use it; combined with a blood-urea estimation, in all cases of doubt. I look upon a poor urea-concentration test as an absolute indication for the termination of pregnancy. The chances of permanent renal damage in these cases are far greater than is generally supposed, and in my opinion this risk does not justify very prolonged treatment of pre-eclamptic conditions.

In the table on eclampsia in Dr. Thomson's report for 1937 I note that cases Nos. 6 and 10 were in hospital twenty-six and twenty-three days respectively before

delivery; No. 6 had four intra-partum fits, and in No. 10 the fits recurred in labour. Might not early induction have lessened the danger?

While congratulating Dr. Thomson on the excellence of his results for 1937, I feel that he must have had an extremely anxious time while the seventeen cases of eclampsia were in hospital.—I am, etc.,

RUTH C. THOMAS,
F.R.C.S.D., M.C.O.G.

Croydon Obstetric Service,

Treatment of Placenta Praevia

SIR,—I have seen, somewhat belatedly, in the *Journal* of June 18 (p. 1334) a letter from Dr. Bethel Solomons, one of my former assistants at the Rotunda Hospital, under the above heading. It contains the following extraordinary statement: "I was brought up to believe in the value of vaginal plugging" [for placenta praevia]. Now the people who were responsible for the obstetrical "bringing-up" of Dr. Solomons were the late Sir Arthur Macan, Dr. Hastings Tweedy, and myself. Sir Arthur accepted vaginal plugging somewhat diffidently as a possible alternative to podalic version. Dr. Hastings Tweedy opposed the use of the plug in both his teachings and writings, and I have consistently done the same. Where, then, was Dr. Solomons brought up to believe in its value? Can it be that he confuses unavoidable and accidental haemorrhage, and has come to believe that the older teaching of the Dublin school on the treatment of the latter complication applies also to the former?—I am, etc.,

Christchurch, New Zealand, Nov. 23. HENRY JELLET.

Treatment of Pneumonia

SIR,—I have been interested in the correspondence and reports relating to the above subject which have appeared in the medical press during the last few months, and I have naturally been impressed by the results of the practical application of up-to-date serological and chemotherapeutic methods. I have been struck, however, by the omission of any mention of quinine. I am not of the generation which was privileged to have personal contact with Burney Yeo, but I have had the good fortune to work under those who were taught by him. As a result I have employed very often his effervescent quinine mixture—quinine and citric acid in the one bottle and potassium bicarbonate plus nux vomica or potassium iodide in the other—according to the needs of the moment, and have never had reason to regret it.

Typing of the organism and the use of homologous serum is, of course, an excellent and everyday procedure in lobar pneumonia, but does not always produce equally good results in bronchopneumonia. In the practice of a large infectious hospital, such as that to which I am attached, lobar pneumonia is comparatively infrequent, but bronchopneumonia, in measles and whooping-cough especially, is a common and often fatal complication. Most of the cases are little children, and it is usually impracticable to give quinine by mouth to such young subjects. During the past eight years I have used quinine in the form of "transpulmin," an oily solution of quinine and camphor which is administered by hypodermic injection (Homburg Pharma Ltd., Africa House, W.C.2), and in that time have had occasion to employ it in hundreds of cases, with more than gratifying results. I usually give from 0.5 c.cm. to 1 c.cm. daily for a week, and after a few days' break, if the bronchopneumonic condition has not

shown signs of clearing up, I begin a second course. It is equally efficacious in adult patients. Beyond a purely clinical satisfaction I have no interest in this preparation; but my primary object in writing this letter is to prevent so excellent a drug as quinine from being submerged by the more modern products, and at the same time to place on record my appreciation of a form in which it is usefully and scientifically available.—I am, etc.,

Liverpool, Dec. 10.

ELSIE A. BURNS, M.D.,
Principal Medical Officer, City
Hospital, Fazakerley.

Glycosuria

SIR,—I have read with interest Dr. V. J. Glover's letter (December 10, p. 1224), in which he draws attention to the high incidence of glycosuria found in a group of apparently normal individuals. Of 132 volunteers for A.R.P. work eight men were found to have glycosuria, and Dr. Glover puts this forward as evidence of the frequent occurrence and insidious nature of diabetes. The fact that those persons found to have sugar in their urine "felt well and strong and all save one followed occupations involving hard work" is surely presumptive evidence against the diagnosis of diabetes, and no such label should be attached to them unless they prove to have abnormal blood-sugar curves. I do not think it is unreasonable to express the opinion that most, if not all, of these people who passed sugar at the time of the crisis would subsequently be found to be either sugar-free or to have normal sugar curves.

The mechanism whereby emotional stress produces transient glycosuria is possibly the same as produces diabetes when acting over a considerable period of time; but it would be incorrect to describe such transient examples as the subjects of diabetes. It is recognized that psychological stimuli may produce repercussions on the autonomic and endocrine systems sufficient to cause organic disease, but if every minor disturbance, such as temporary glycosuria during emotional stress, is regarded as evidence of disease it will lead to unnecessary restriction of the lives of many normal persons. Certainly they should be investigated, but their subjective symptoms should be given due weight. If an individual feels happy and well and is able to lead a normal life, it is at least presumptive evidence that he is biochemically correct.—I am, etc.,

Colchester, Dec. 12.

S. A. PROPERT,
M.A., M.R.C.P.

SIR,—It is well known that many cases of unsuspected diabetes are discovered in the course of examinations for life insurance, even when there are no marked objective symptoms, especially in elderly people. But the discovery of glycosuria is an indication for further investigation rather than of final diagnostic significance. I do not suppose Dr. Vincent J. Glover (*Journal*, December 10, p. 1224) intended for a moment to convey that glycosuria and diabetes are synonymous. Eight men in 132 seems rather too high an incidence for true diabetes. Unfortunately Dr. Glover does not say anything about the specific gravities of the urines which gave "rapid and copious reduction."

In the course of many thousand examinations I have more than once found glycosuria of a psycho-adrenal origin in highly nervous subjects who on further examination had normal glycaemia, sugar tolerance, and renal threshold.

Dr. Glover mentions that all save one of the eight men "followed occupations involving hard work." If the

urines of a Rugby football team be examined at the end of a hard game many will be found to contain sugar, due to the escape of temporary hyperglycaemic sugar from the blood when the demand of the muscles has ceased and the physiological activity of the adrenals is slowing down as the body returns to a condition of comparative rest.

A few months ago I was puzzled by finding that a large number of female urines gave a copious reduction of a peculiar light purplish-red colour, both with Fehling and Benedict (0.3 c.cm. of urine to 5 c.cm., boiled for two minutes, and cooled by standing). After a lengthy investigation it was found that all the individuals concerned munched throughout the day large quantities of chocolate of a certain brand, which they bought at their canteen. On their abstaining from this chocolate the reaction disappeared from the urine.

In persons showing glycosuria without any objective symptoms of diabetes, whose glycaemia and sugar tolerance are normal, I always look for septic foci, especially in the teeth, tonsils, and gall-bladder. The association is commoner than is generally realized.

In conclusion I would like to stress the importance of scrupulous care, both as regards reagents and technique, even in a simple routine matter such as urine testing. It is easy to obtain fallacious results, especially when so-called "convenient" methods are employed. Glucose is not the only substance which will reduce copper. The fermentation test is easily applied and, if the ordinary test solutions are reduced, should never be omitted. There is a minute trace of sugar even in healthy urines; and I have seen a reduction in specimens highly concentrated through hard muscular work and copious perspiration. Glycosuria is also found in certain subjects of gastrointestinal anastomosis—but, as Kipling says, that is another story.—I am, etc.,

Brookwood, Surrey, Dec. 10. H. M. STANLEY TURNER.

Health and Agriculture

SIR,—It was with the greatest possible pleasure that I read in the *Journal* of December 10 (p. 1208) your leading article "Health and Agriculture." As one who is intensely interested in the subject I hope your article will stimulate the minds of all who read it, so that by united effort some form may be fashioned out of the present chaos. You gave pride of place to milk as a "health-protective" food, and you go on to say that "if it were increased by one-third of a pint per day it would still be far below the level which is desirable on nutritional grounds; yet such an increase would entail an expansion of our natural milk output of no less than 65 per cent. At the present rate of productivity this would require the maintenance of 2½ million more cows."

In reply to this statement, I believe I am quite accurate in saying it would not pay. In the first place, is this to be raw milk or pasteurized? If the former, then I can say definitely that to produce Grade A T.T. milk at present prices does not pay. The intensive grassland management required, the loss on cows failing to pass the tuberculin test, depreciation, etc., are such a handicap that the farmer is lucky if his accounts balance. During the last twelve months the *Field* published a series of articles which showed the sorry plight of agriculture in England. Letters have appeared more recently on the same subject in *Horse and Hound*, and, although not unanimous, the impression left on one's mind is the absolute futility of farming at present. Store cattle can be bought in the months of April and May, and sold in

November at a loss. To fatten beasts therefore under present conditions is a speculative business.

The figures published showing the use made by the farmers of the lime and slag subsidy are disappointing; they reveal how little use relatively was made of this grant. May it be assumed from this that even the reduced cost was outside the means of the farmers? An analysis of the cost of production of vegetables and eggs would be sorry reading, I feel sure, but I have no practical experience of this. The towns have swallowed up the population; food is only regarded in the light of what it costs in the shops, and little thought, if any, is given to the method and cost of its production; the horse has been supplanted by the motor; hay, oats, and straw had a ready market when the horse did the work; nothing has been devised to replace this loss to the farmer. The recent crisis stirred up a great interest in A.R.P. work. Can something not be done to excite the interest of all in the much more important subject of food in peace and war?—I am, etc.,

Belfast, Dec. 13.

W. A. ANDERSON.

SIR,—I should be greatly obliged if someone would demonstrate to me the appositeness of the oft-repeated slogan, "effecting a marriage of agriculture and nutrition," which you quote in a leading article on Astor and Rowntree's book in the *Journal* of December 10. Since "agriculture" desires to obtain as much as possible for its products—and "nutrition," naturally, to pay as little as possible for them—to my mind the prospective partners to the marriage are faced from the outset with a fundamental disagreement, which would tend to anything but conjugal harmony and constructive co-operation. In effect, this difference on the basic principle essential to such a pact separates them as far as it is possible for any incompatibility of temperament to do so. Nor—marriage or no marriage—can I see any justification for the prediction by the enthusiasts of a paradise awaiting agriculture as a result of its association with nutrition. Indeed, the fact that what is beneficial for the one is by that very fact detrimental to the other renders the fulfilment of such a forecast unlikely in the extreme.

If one considers, for instance, the case of milk, as matters stand we have on the one hand internal tariffs, subsidies, and bribes (to employ Astor and Rowntree's wording), all of which are disadvantageous to the "demanders." "Suppliers," however, will be advantaged for a time; but ultimately demand will be curtailed and either price will have to be reduced or some "suppliers" go out of business. On the other hand, in free-marketing conditions, with the operation of competition among "suppliers," "demanders" would at first have an advantage, which, however, would be rectified when, certain "suppliers" having gone out of business as the result of the competition, the demand would rise out of proportion to the available supply. There is the further point to be considered, and a very significant one from the point of view of nutrition, that in the first set of circumstances the tendency over a period would be towards diminished consumption of milk per head and a diminished production of it for the country as a whole; while, in the second case, the tendency would be in the opposite direction towards an expansion in both instances. We have here simply an illustration of the operation of Newton's third law of motion (applied to economics, as it can be) that to every action there is an equal and contrary reaction, the net result being a tendency to return always to an intermediate mean value.—I am, etc.,

Aberdeen, Dec. 12.

J. P. McGOWAN.

Primary Abdominal Tuberculosis

SIR.—We are grateful to Sir Henry Gauvain for his complimentary reference to our article pointing out the danger of primary abdominal tuberculosis in young children. We fully agree that in older children danger of dissemination of the disease from the primary focus is not so great and that early diagnosis is not so difficult as in early childhood. But in our paper we considered only children up to 5 years of age whose disease, before the onset of meningitis, was at the stage of a recent primary focus, the anatomical basis of which consists usually of a few moderately enlarged glands. No definite sign of this lesion exists, and the general initial symptoms given by Sir Henry Gauvain are too common to suggest tuberculous infection. One of us (S. E.) investigated from this point of view children complaining of vague abdominal symptoms and found that the tuberculin test in these children was less often positive than in children without abdominal symptoms. This shows that there is little likelihood of there being a causal connexion between a primary tuberculous focus and vague abdominal symptoms in children. By the time that secondary local or distant manifestations appear (for example, the "doughy abdomen" which Sir Henry quotes as presumptive evidence of tuberculous) diagnosis is not difficult and the risk of dissemination is small. As we emphasized in our paper, it is before the disease is clinically recognizable that meningitis is likely to occur, and for this reason we stressed the necessity for prevention of infection.

It may be of interest to note that since our paper went to press four other cases of tuberculous meningitis following a primary abdominal focus of infection have come to necropsy at this hospital.—We are, etc.,

Human Oil and Adherent Scars

SIR.—With reference to the article by Mr. Cecil P. G. Wakeley in the *Journal* of September 17 (p. 618), may I state that eighteen years ago I used injections of human oil, or as I called it melted human fat, in the treatment of adherent scars on the face in soldiers. Although it gave apparently satisfactory results at the time I gave up its use because it seemed to me that the scars tended to become re-adherent after the fat had completely absorbed, as it always did. A much more satisfactory and lasting method is to divide the adhesions subcutaneously and insert thin autogenous fat grafts, which do not tend to absorb, and the results are in my experience more efficacious and cosmetically much superior.—I am, etc.,

Wellington, N.Z., Nov. 23.

H. P. PICKERILL.

For many years Mr. and Mrs. Alexander Farquharson have been developing and making known the idea that the study and teaching of sociology and civics should be based on observation and field work, and they are now organizing a winter school of sociology and civics from December 30 to January 6 at the London House of Citizenship in South Kensington. The Royal Borough of Kensington will provide the material for observational work and field studies dealing with the natural environment, historical development, and present-day social and economic conditions. Mr. and Mrs. Farquharson will have the assistance of Dr. Marie Jahoda, formerly of Vienna. Particulars may be obtained from the Hon. Organizer of Field Studies, Le Play House, 35, Gordon Square, W.C.1.

Obituary

SIR COOPER PERRY, G.C.V.O., M.D., LL.D., F.R.C.P.

Consulting Physician, Guy's Hospital

The death of Sir Cooper Perry on December 17, at the age of 82, removes an outstanding character and a mind of remarkable strength and versatility.

Edwin Cooper Perry, son of the Rev. E. C. Perry, had a brilliant career at Eton and King's College, Cambridge, which he entered as a scholar. He was Senior Classic in the Classical Tripos of 1880, and immediately afterwards was elected a Fellow of King's. While still holding this fellowship he studied medicine at the London Hospital, taking the M.R.C.S. in 1885, the M.B. soon afterwards, and proceeding M.D. in 1888. During his period of residence at King's he was assistant demonstrator of anatomy in the Cambridge Medical School. At the London Hospital he served as house-physician and house-surgeon.

Sir Cooper Perry's long connexion with the teaching staff of Guy's Hospital began with a demonstratorship in morbid anatomy. He was soon afterwards elected assistant physician, and held office in the medical school as lecturer in materia medica, in dermatology, and in medicine, and he was given charge of the skin department. He was also examiner in materia medica and pharmacology for the University of London, in medicine for the University of Cambridge, and in materia medica and medicine for the English Conjoint Board. His election as F.R.C.P. was in 1894, and he served on the Council of the College in 1913-15. He wrote papers for the *Guy's Hospital Reports* on malignant disease (with Dr. Lauriston Shaw) and on diseases of the duodenum. For many years he combined clinical and teaching work at Guy's with the post of superintendent of the hospital, which gave scope for his great powers of administration, and on retiring from the staff he was elected consulting physician and a governor of the hospital and school. In 1903 he received the honour of knighthood. From 1920 to 1926 he was Principal Officer of the University of London, after serving two years as Vice-Chancellor. On October 20, 1926, the Senate adopted a resolution placing on record its high appreciation of the work he had done for the University.

From 1898 onwards Sir Cooper Perry was closely associated with King Edward's Hospital Fund for London, and he served on its General Council and Management Committee and presided over its Distribution Committee. He had held many other public offices, including membership of the Army Qualifying Board, the Voluntary Hospitals Commission, and the Departmental Committee on Postgraduate Medical Education in London, and chairmanship of the London School of Hygiene and Tropical Medicine, of the Chartered Society of Massage and Medical Gymnastics, and, after his retirement to Worthing, of the local hospital. He had also been chairman of the

Army Hospitals Commission and a governor of Holloway College. In 1927 he went to Egypt to reorganize the work of the Faculty of Medicine in the Egyptian University at Cairo, and remained there for some time as director. He was created G.C.V.O. in 1935.

Mr. H. L. Eason, C.B., C.M.G., Principal and late Vice-Chancellor of the University of London, sends the following appreciation:

"Nihil quod tetigit non ornavit" is, I think, the best epitaph for Sir Cooper Perry. He would have made an ideal Civil Servant. A classical scholar, a musician, a great physician and pathologist, an administrator of unusual quality, in all spheres of his activity he did not much care who got the credit for anything done so long as it was done, usually by him. Those who worked with him behind the scenes knew his value, his massive intellect, and his constructive capacity. The outside world knew him hardly at all. This was due to a peculiar combination of intense shyness and a justifiable vanity. He hated public speaking, and in his hospital days was so nervous about giving a lecture to students that he never slept the previous night. When he did lecture he did so with his eyes on the ground in manifest discomfort. His shyness led him to hide behind a certain brusqueness of manner which was not always appreciated by his acquaintances. Those who got behind this screen soon found that he was intensely human, kind-hearted, and sensitive. He was extraordinarily fair-minded and just, and would make allowances for everything but mental dishonesty. Moral delinquencies he could forgive, but anyone who prostituted his intellectual gifts to base purposes or was tortuous in his mental dealings passed into the limbo of outer darkness so far as he was concerned.

In the world of medicine he was the last of the great succession of morbid anatomists at Guy's Hospital. His manual skill in conducting a necropsy was perfect, and his knowledge of morbid anatomy encyclopaedic. His bedside teaching was extremely effective, owing to his grasp of both clinical knowledge and morbid anatomy, and to be his house officer was the delight of generations of Guy's men. In the world of music his important achievement was the revision, in conjunction with Dr. A. H. Mann, of the Anthem Book in use at King's College, Cambridge, and throughout his life he was a devotee of the more formal and classical music. It was in administration, however, that he made his mark. Coming to Guy's Hospital from the London Hospital in the early nineties of the last century, he found that it had been asleep for thirty years. He reorganized its constitution, its administration, and its finances, and for the twenty-eight years that he was its superintendent it flourished as a happy institution free from acute financial anxiety. He reorganized the Army Medical Service after the South African War and was responsible for the building of the present Army Medical College at Millbank. He was for many years on the council of King Edward's Hospital Fund for London and the chairman of its Distribution Committee. In this capacity his profound knowledge of hospital administration and his understanding of the peculiar problem of teaching hospitals were invaluable.

He had a mastery of concise and lucid English prose. He was a firm believer in that precept of Quintilian's that "Care should be taken not that the reader may understand if he will, but that he must understand, whether he will or not." It was this passion for accuracy that led some people to think that he was fussy over verbal corrections. As a matter of fact he never corrected a document that he did not improve. A few words changed,

a sentence reconstructed, and the memorandum was at once on a higher plane. When he himself was in doubt as to the clarity of a sentence he had the habit of translating it into Latin and then back again into English. If he could get the sense clearly in Latin it must be clear and he was satisfied.

Women either admired him or disliked him intensely. There was no middle course for them. He had a habit of paying back-handed compliments that did not make for feminine appreciation. Those who realized his great human qualities behind the lack of social graces were his devoted friends for life, and he in turn repaid their devotion with countless kindnesses. In his form he was bulky and ungainly. No one seeing him at any time in the last forty years would ever have imagined that he had played the wall game at Eton. He never walked if he could take a cab, and in his later years physical exercise was unknown to him.

His success as an administrator was due to the fact that he always had a constructive policy of his own for every problem. He had a contempt for the destructive critic who had no constructive ideas. As a committeeman one found that he had always read the minutes of the previous meeting and had corrections to make if necessary. He had always read his agenda and had his own ideas as to the action to be taken; and, finally, he had his own ideas committed to writing in the form of a resolution. A man who does this nearly always carries a committee with him, especially when his ideas are both well-considered and original. Resembling the late Lord Salisbury in his face and figure, he in his mind also resembled an Elizabethan statesman such as Cecil. Weighty, wise, deliberate in judgment, knowing just when to wait and watch and when to take decisive action, he would have been a worthy member of Queen Elizabeth's famous Councils of State. He could draft a document that could be subtle without deceit and uncompromising yet courteous.

He lived his life as he wished it. Regardless of money or public applause or preferment, he chose the reality of power and influence rather than the trappings of publicity, and he used his incomparable mental gifts entirely to the public good. He well deserved one of his favourite epitaphs—"Inservivit saeculo suo."

Many will have heard with deep regret of the death of HUGH DAVIES-COLLEY, O.B.E., M.B., F.R.C.S., who has been responsible for much of the surgical work of the Aldershot Command since 1915. The spirit of surgery coursed in his veins, for he was the son of a famous Guy's surgeon, and his mother was the daughter of a former treasurer of Guy's. The family record is a most illustrious one, for not only have his father and younger brother held posts of high honour on the surgical staff of Guy's, but each has also served the Royal College of Surgeons of England in several distinguished capacities. His sister, who herself predeceased him, was a famous woman surgeon and was on the surgical staff of several hospitals in London. Educated at Westminster and Trinity College, Cambridge, Hugh Davies-Colley received his clinical education at Guy's. He obtained the Fellowship of the Royal College of Surgeons in 1904, but it was the European war that really discovered him as a surgeon. Davies-Colley was appointed to the staff of the Cambridge Military Hospital, Aldershot, at a time when Sir Arbuthnot Lane was organizing the medical and surgical arrangements of the Command; at first the genito-urinary department was allotted to him, and to many his name will conjure up memories of a kindly, indefatigable, and in those days bearded surgeon wandering through the long corridor at any hour of the day or night armed with his "periscope." He ultimately became the chief surgeon

to the Cambridge Hospital, and held this position until his death. He had a most lovable disposition; his temper was never known to be ruffled; I do not believe that he had an enemy in the world. It was indeed fitting that his coffin should have been borne on other men's shoulders from the hospital to which he had given his best for nearly a quarter of a century.—G. G.-T.

The death of Dr. JOHN WHITIER CLEVELAND, J.P., of St. Albans, on November 11, at the age of 61, removed one who had been conspicuous for his work in various spheres of public service; it brought sorrow to a large circle of his medical colleagues. Born at Havant in Hampshire, he was educated at Charterhouse and St. Bartholomew's Hospital. Having taken the diplomas M.R.C.S., L.R.C.P. in 1904, he was assistant house-surgeon at the Royal Berkshire Hospital, Reading, and then resident anaesthetist and house-surgeon. He began to practice in St. Albans in 1906, where he continued at work until his death, apart from a period of war-time service, during which he was at first resident surgeon officer at the King George Military Hospital for Officers, and later medical officer in charge of the Endsleigh Palace Hospital for Officers. In 1919 Dr. Cleveland was appointed to the medical staff of St. Albans Hospital, and ultimately became honorary consultant surgeon and a member of the House Committee. He was one of the founders of the St. Albans Division of the St. John Ambulance Brigade, and its surgeon. He was appointed an Associate of the Order of St. John in 1923, and three years later was promoted to the rank of Officer of the Order in view of his great services. For nearly sixteen years he was a member of St. Albans City Council, and was mayor of the city in 1922-3; he was also active in support of the Nursing Association and the British Legion. He was a prominent Freemason; W.M. of the Halsey Lodge in 1928, and a Past Provincial Grand Deacon of Herts, in both the Craft and the Royal Arch Degrees. A keen Conservative, he was for many years a member of the executive council of the divisional association, and chairman of the East Ward Association. He captained the Verulam Golf Club in 1922, and had presided over the St. Albans Cricket Club. He was a strong supporter also of the St. Albans Football Club, and its honorary surgeon.

Dr. GRANT ROSS GRIBBEN, formerly a member of the Trinidad Medical Service, died at Brummana, Lebanon, on November 19, and was buried at Beirut in the Anglo-American cemetery. A student of Glasgow University, he graduated M.B., Ch.B.Glasg. in 1924, and afterwards took the D.T.M. Liverpool. Dr. Gribben during his period of service in Trinidad was medical officer of health for Brighton-la Brea rural sanitary district and port medical officer. He was elected a member of the British Medical Association by the Glasgow and West of Scotland Branch immediately after graduation, and five years ago he read to the Trinidad and Tobago Branch a paper on mass treatment with plasmoquin, which was fully reported in the *British Medical Journal* of November 13, 1933.

Dr. WILLIAM FOSTER, medical officer of health under the Shipley Urban District Council for thirty-four years, died at his home on November 27 at the age of 83. The son of Dr. John Foster of Bradford, he was educated at Bradford Grammar School, Epsom College, and the University of Cambridge, taking the clinical part of his course at the Leeds Medical School. He obtained the M.R.C.S. and L.S.A. diplomas in 1879, the Cambridge M.B. in 1885, and the D.P.H. in 1892. After working as house-physician and resident medical officer at the Bradford Royal Infirmary Dr. Foster travelled to Australia, South Africa, and America as a ship surgeon. He began practice at Shipley in 1885, and was appointed medical officer in 1895 and school medical officer in 1906. He acted for some time as medical superintendent of the child welfare centre and consulting surgeon to Sir Titus

Salt's Hospital. He had been a member of the British Medical Association for thirty-five years at the time of his retirement from active work in 1929.

Dr. JOHN H. FARDON, a well-known practitioner of Birkenhead, died at Oxtou, Birkenhead, on November 28, 1938, at the age of 75. After qualifying M.R.C.S., L.R.C.P., he became demonstrator in anatomy at Bristol University, which position served him in good stead for his future career as a surgeon and general practitioner. He later held resident posts in the Liverpool hospitals and began general practice in Birkenhead in 1894, in which town he remained in active practice until the day of his death. He was appointed honorary surgeon at the Birkenhead General Hospital, then called the Borough Hospital, in 1902, giving his time and skill unstintingly until 1926, when he became a consultant surgeon. During the late war Dr. Fardon, besides doing his work at the hospital and in general practice, was medical officer to one of the larger school military hospitals in Birkenhead, and it is on record that he only missed meeting four of the ambulance trains arriving day and night during the whole of the war years. For this excellent work he was awarded the M.B.E. He had been a member of the British Medical Association since 1896. A colleague, "E. L. M.," writes: Dr. Fardon was a most enthusiastic worker for the British Red Cross, in which Society he took a tremendous interest and was for many years an examiner and instructor in the Birkenhead area. He was a man of high standing in his profession, conscientious, keen, and kindly, although of a retiring disposition. He was greatly esteemed and looked up to by his younger colleagues, who recognized his experience and that he was one of the real old type of general practitioners—fast fading away. Beloved by his patients, he will be greatly missed by all, and our united sympathies are extended to his wife and daughter.

Dr. CUTHBERT BRACEY DALE, who died on December 9 at Weston-sub-Edge, Gloucestershire, had practised for many years at Edgbaston, where he had been born in 1870. A student of St. Bartholomew's Hospital, he qualified as M.R.C.S., L.R.C.P. in 1891, and after serving as house-surgeon at Bart's and at the Bucks General Infirmary, Aylesbury, he was for two years clinical assistant to the Royal Eye Hospital, South London. While in general practice at Edgbaston he was certifying factory surgeon for East Birmingham, and for some time anaesthetist to the Birmingham Ear and Throat Hospital and to the Birmingham School Clinic. Dr. Dale was a member of the Midland Medical Society, and joined the British Medical Association in 1901.

On December 14 EDWARD PHILIP, M.B., C.M., died suddenly at his home in Roehampton Lane, London, S.W., aged 67. The son of William Philip, shipmaster, he had his medical training at Aberdeen University, where he graduated in 1893. At an early age he started practice in a working-class district of South-West London, and his admirable professional abilities soon resulted in constant overwork. As time went on his reputation grew steadily and rapidly, and he was able to move into Redcliffe Gardens, where he practised for many years. Without making any pretensions to academic distinction, Philip had those qualities of observation, judgment, and sympathy which not merely made him deservedly successful but ensured also the affection of his patients. Some few years ago his health began to arouse anxiety—quite probably caused by the severe strain of his early days in practice, when he was accustomed to attend 200 midwifery cases a year at microscopic fees (or none at all)—and about six years ago he retired, settling ultimately opposite the gates of Roehampton Club. Philip was a man of real and unostentatious piety; he was a storehouse of amusing anecdotes, mainly Rabelaisian; and he had hosts of devoted friends among his professional colleagues, in his practice, and in the world at large. His

wife died several years ago, and he is survived by two sons and two daughters. He joined the British Medical Association in 1907, but never took office, though he was keenly interested in its affairs.

Dr. ALEXANDER MACALISTER, Walt Whitman's physician and friend, and one of the first in America to use diphtheria antitoxin, died at Camden, New Jersey, on November 22, aged 77.

JORGEN PETER MÜLLER, originator of the Muller system of home gymnastics and for many years principal of the Muller Institute in London, died at Aarhus, Denmark, on November 17, at the age of 73.

Medico-Legal

A HERBALIST ACQUITTED

A case tried before Mr. Justice Croom-Johnson at the Manchester Assizes at the end of November* raised some interesting points concerning unqualified practice.

Trial at Manchester Assizes

A "consulting herbalist" named Thomas Hugh Wilbraham was charged with the manslaughter of a youth of 22, whose father had put him under Wilbraham's care for diabetes. Mr. J. G. Lynskey, K.C., prosecuting, said that Wilbraham represented himself as being skilled to deal with the disease of diabetes, but had not shown the necessary skill or used the necessary care, with the result that the boy had died on September 5. In March, 1937, the boy's father had noticed that he was drinking much water and becoming drowsy. The father consulted a doctor, who diagnosed serious diabetes and sent the boy to Dr. Norman Kletz, who tried a diet for two or three weeks and then decided that the boy required insulin injections. Unfortunately, before that treatment was undertaken the father had heard that insulin was not a cure for diabetes but only a stabilizer, and got the impression that diabetes could be cured by a herbalist or osteopath. For a time he placed his son under the treatment of a woman herbalist, but in November, 1937, he went to Wilbraham. The accused, said counsel, told him that he specialized in the treatment of diabetes, had had successful results with other patients, strongly disapproved of the use of insulin, and included in his treatment the use of herbal medicine which caused the pancreas to function again. He was confident he could cure the boy. His charges were 10s. a visit. He did not prescribe any special diet except that the boy should restrict himself as much as possible to green vegetables. He began treatment in January, and in August the boy again broke down, became weak in his legs, and was terribly thin. Wilbraham, however, said he was very pleased with his condition, and that he was giving "pancreatic juices" in the medicine. Later he said that the sugar was down 14 points. In September the boy could not stand, and his father asked Wilbraham by telephone whether he should get a doctor. The accused replied that he did not think it necessary. Next day he came to see the boy at the request of the father and said that the sugar was less, that there was not much chance of coma, that the boy was suffering from a poisoned stomach, and that he would give him medicine to put him right. Next morning the boy was worse, and he died in hospital next day.

In cross-examination by Mr. E. J. Hemmerde, K.C., the father admitted that he would not have accepted Wilbraham's treatment along with insulin, but he denied that Wilbraham had suggested insulin. Re-examined, he said that two doctors had advised the use of insulin, but he had not followed their advice because a friend gave him a paper which said that

diabetes could be prevented and cured if it had not progressed too far, provided the patient had not taken too much insulin.

Dr. Patrick Fay said that he had seen the boy in March, 1937, and that on April 23 he had stressed the need for insulin. Dr. Kletz said that in this case it was probable that without insulin life would have been materially shortened. Dr. W. H. Grace, the pathologist who made the necropsy, expressed the opinion that if the boy had started to take insulin in January he would now be living a normal active life.

Wilbraham, giving evidence on his own behalf, not only denied having neglected to give insulin, but said that the use of insulin with his treatment was definitely helpful in some cases and essential in others. He asked his diabetic patients to get insulin prescribed by a doctor. He was not allowed by law to prescribe or use insulin. Some of his present patients were using insulin under doctors' directions. In August he had told the father and the son that the son must have insulin. The son said he did not want it and the father said he could not have it. Later he said to the father, "Without the use of insulin I am afraid you are going to make a terrible mistake." The father walked out of the place in disgust. Wilbraham told him that he must call in a doctor right away, and that if he did not Wilbraham would send one. The father replied that he did not care for the doctors round there; he had had some trouble with them before. From first to last, said Wilbraham, he treated the boy according to the knowledge he had, and did everything he could to help him. If he had been allowed to use insulin he would have compelled the boy to have it. The death was accelerated by the failure to give insulin.

The judge, in summing up, warned the jury that they were not trying the question whether treatment by registered medical practitioners according to ordinary practice was better or worse than treatment by herbal medicine. The question was whether Wilbraham had advised or failed to advise insulin, or had advised against its use. The jury found him not guilty and he was discharged.

The Services

DEATHS IN THE SERVICES

Surgeon Commander ALFRED THOMAS GAILLETON, R.N. (ret.), died at Valparaiso on November 29. He was educated at Edinburgh University, where he graduated M.B., Ch.B. in 1898. He entered the navy soon after qualifying, became surgeon commander on August 10, 1915, and retired after the war. After his retirement he took the D.P.H. at Cambridge in 1923. He served in the war of 1914-18, receiving the medals.

Major-General JOHN JOSEPH GERRARD, C.B., C.M.G., late R.A.M.C., died in London, from the effects of an accident, on December 14, aged 71. He was born in Dublin on October 22, 1867, and was educated at St. Augustine's College, Ramsgate, and at Trinity College, Dublin, where he graduated M.B., B.Ch., B.A.O. in 1888. He entered the Army as surgeon captain on July 23, 1891, and was specially promoted to surgeon major for services in the Tirah Campaign on May 20, 1898. Incidentally he was the last officer promoted to surgeon major before the grant of the military titles. He became lieutenant-colonel on July 28, 1906, colonel in the long list of war promotions on March 1, 1915, and major-general on January 24, 1918, and retired on January 27, 1922. He served on the North-West Frontier of India in the Tirah Campaign of 1897-8, when he was mentioned in dispatches in the *London Gazette* of April 5, 1898, received the frontier medal with two clasps, and was specially promoted to surgeon major; in the South African War from 1899 to 1902, when he took part in the action at Colenso and in the relief of Ladysmith, and in operations in the Orange River Colony and the Transvaal, and received the Queen's medal with three clasps and the King's medal with two clasps; and throughout the war of 1914-18, when he held various administrative appointments at the fronts in Flanders and France, was mentioned in dispatches in the *London Gazette* of June 15, 1916, January 4, 1917, and May 29, 1917. He received the C.B.

* *Manchester Guardian*, November 30 and December 1.

in 1917 and the C.M.G. in 1919. After the war he was principal medical officer in Ireland from 1920 to 1922, during the Sinn Féin rebellion. He was appointed Honorary Physician to the King in 1920. In 1898 he married Miss Mabel Repton, who survives him with two sons and two daughters. His eldest and third sons were killed in action in 1918.

Lieutenant-Colonel SIDNEY ARTHUR WILKINSON, chief medical officer of the Bombay, Baroda, and Central India Railway, lost his life on November 26 after a railway accident at Barwani on that line. Apparently no one was injured in the accident itself; some carriages were derailed and Colonel Wilkinson had got out of his carriage and was walking alone the line to see if there were any casualties when he suddenly collapsed and died of heart failure. He was educated at St. Thomas's Hospital and took the M.R.C.S., L.R.C.P. in 1914, and subsequently, when on leave in England, the D.T.M. at Liverpool in 1927, and the D.T.H. in 1928. After acting as house-surgeon at Wolverhampton Hospital he entered the service of the Bombay, Baroda, and Central India Railway and had risen to be its chief medical officer. He took a commission in the Indian Railway Volunteers on May 1, 1915, subsequently joining the Indian Auxiliary Force Medical Corps, in which he held the rank of major from May 1, 1927, and recently reached the rank of lieutenant-colonel. At the time of his death he was expecting to go home soon on furlough. He had been a member of the British Medical Association since 1919. He leaves a widow and daughter, who were in Bombay when he died.

Lieutenant-Colonel FREDERICK DEBAND SHIRING FAYRER, I.M.S. (ret.), died at Eastbourne on December 2, aged 69. He was born on October 28, 1869, the fifth son of the late Sir Joseph Fayrer, Bt., K.C.S.I., President of the Medical Board, India Office, for over twenty years—1873 to 1895. He was educated at Cambridge University, where he graduated B.A. in 1891 and proceeded M.A. in 1894, and at Charing Cross Hospital, and took the M.R.C.S., L.R.C.P. in 1896. He entered the Indian Medical Service as surgeon lieutenant on January 29, 1898, became lieutenant-colonel after twenty years' service, and retired on April 8, 1925. He served in the war of 1914-18, on the North-West Frontier of India in 1914-15, in the Toshi Valley. He had been a member of the British Medical Association since 1901.

Universities and Colleges

UNIVERSITY OF OXFORD

The following medical degrees were conferred in Congregation on December 10:

D.M.—D. G. Ferriman, H. R. Bathurst-Norman.

B.M.—E. M. Poulton, J. Scholefield, L. G. C. E. Pugh, R. G. W. Osterhew, C. D. Cormac, E. L. James, J. C. G. Abraham, E. H. Hiley.

UNIVERSITY OF CAMBRIDGE

At a Congregation held on December 9 the following medical degrees were conferred:

M.D.—W. A. Elliott, A. K. Monro, L. C. Cook.

M.B., B.Chir.—A. W. Bone, *G. V. Steward, K. E. Bond, A. Winder, A. H. Masina, R. S. Saxton.

M.B.—F. H. Masina, A. H. Gurney.

* By proxy.

UNIVERSITY OF LONDON

At a meeting of the Senate, held on December 14, the Graham Scholarship in Pathology was awarded to R. M. Calder, M.B., Ch.B.

Dr. H. E. A. Boldero has been appointed as one of the representatives of the General Medical Schools on the Senate for the remainder of the period 1938-42 in succession to the late Professor Leonard S. Dudgeon.

The Royal Hospital, Wolverhampton, has been approved for three years as from October, 1937, for the purposes of the External Diploma in Clinical Pathology.

Foundation Day was celebrated on November 24, when the Chancellor, the Earl of Athlone, F.R.S., held a reception at Senate House. Graduates who had obtained degrees since May were presented to the Chancellor.

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—J. B. Griffiths, J. L. J. Honeywill (University Medal), M. E. MacGregor, C. M. Miller, C. S. Smith, *R. B. Terry, *Margaret D. Thomas, Mary E. E. Ward, B. S. Acharya, A. G. Apley, J. R. Ascott, Romana G. Bartolot, D. McN. Beaugis, R. D. Blackford, Natalia S. Blumenfeld, D. J. A. Brown, K. C. Brown, Margaret M. Burton, W. E. Clarke, J. C. A. L. Colenbrander, Dorothy L. Crossley, E. R. Davis, D. A. Davies, Joan M. St. V. Davies, A. S. Dods, A. M. Edwards, J. A. C. Edwards, Phyllis M. Edwards, B. H. Ellis, D. G. Evans, J. A. P. Evans, C. C. Ivill, C. G. Fagg, B. R. Fink, D. S. Foster, H. Foster, J. P. Fox, D. F. Freedy, Yvonne M. Garland, Margaret F. Gilson, Janet D. Gimson, H. M. Goldberg, Jean E. Grant, L. J. Grant, S. I. Green, C. L. Greenbury, W. S. Hacon, J. A. G. Hair, M. Halberstedter, N. W. A. Harvey, Doreen Jamieson, S. M. Jenner, A. Jordan, J. B. Kinnmonth, C. C. Kirby, G. S. A. Knowles, G. Kruttschae, A. S. Lee, D. R. Levinson, C. V. Lewis, A. W. Little, K. N. Lloyd, M. Lubran, Margaret E. McLaughlin, R. J. H. McMahon, D. E. Macrae, Elizabeth C. Marshall, H. A. C. Mason, S. W. Maxwell, Mary D. Mellersh, P. S. Meyrick, G. D. N. Milne, Elizabeth M. Mitchell, J. D. N. Nabarro, Gladys L. Neill, C. S. Nicol, A. J. Nimmo, D. E. Parry, Edith A. S. Parry-Evans, T. Partington, K. G. Pascall, Ruth Penlon Jones, Gloria H. Platt, S. S. F. Pooley, D. W. Pugh, Elizabeth C. Randall, W. J. Rees, Nora Reid, Nancy E. G. Richardson, R. B. K. Rickford, A. C. Rickis, A. T. M. Roberts, L. I. W. Salmon, D. K. Sambrook, C. R. Savage, W. J. Shannon, P. S. Smith, G. Shcncron, M. M. Shrinagresh, J. R. Simpson, J. H. Smart, Margaret D. Snelling, G. R. Staley, Margaret M. Strange, Mary R. Thompson, L. C. Thomson, K. B. Thornton, J. Todd, Betty Walker, J. W. B. Waring, C. P. Warren, W. W. West-Watson, M. H. G. White, J. H. Whittles, R. F. Wyatt, G. Wynn Williams, R. O. Yerbury. *Part I:* H. Auger, Diana E. Barbour, Patricia E. Barclay, Rosalind S. Barclay, G. A. Beck, Mary B. Bensusan-Burt, H. E. Bentley, A. C. Bingold, R. A. Blair, Elizabeth Broadhead, T. H. W. Clarke, J. V. Davies, M. E. Davies, A. R. Dearlove, W. Donkin, Jean M. Drury-White, Jean L. Edwards, R. G. Evans, Edith F. Fettes, E. L. Frankel, P. Frankel, J. M. French, Kathleen M. French, L. V. Gimson, G. L. Haine, V. W. J. Hettrud, C. A. Jackson, G. M. Killpack, R. A. Kings, P. D. C. Kinnmonth, Dorothy M. S. Knott, Joan V. Laughlin, G. D. Lumb, L. Nancekiewicz, S. Oram, A. S. O'Leary, D. J. Paddison, G. A. Robinson, R. G. Robinson, A. F. Russell, R. W. B. Scott, I. A. G. Seaton, Margaret M. Shrubbsall, Joyce R. Simmonds, F. M. S. Smith, T. D. Spencer, B. L. C. Stanley, W. M. Stephens, Katharine W. Stuart, W. F. T. Tatlow, Norah G. Taylor, J. L. Temple, Elise M. Terry, R. D. Tonkin, Elizabeth Topley, F. G. Tucker, A. J. Walker, A. F. Wallace, M. Watkins, Alice Yates. *Group I:* L. D. Arden, R. H. Barrett, Mary Brandon-Jones, G. L. Burgess, J. Burton, Mercy S. Cam, H. B. O. Cardew, C. D. Chilton, H. D. Cockburn, P. P. Crean, T. T. Davies, J. J. Davis, Ursula M. Dick, J. E. Dickson, C. J. Evans, W. K. Frewen, P. A. Gardner, Beryl M. Gee, J. Henry, R. N. Houlding, Barbara J. Hussey, M. T. I. Jones, R. R. McSwiney, F. P. S. Malone-Barrett, H. Matthews, A. Miller, H. E. Moody, Rosie Morris, R. E. Newman, Sylvia D. Orchard, J. F. Petrides, G. L. Pitt, A. S. Porter, J. Sondheimer, Susan M. Tracy, Joan Wagstaff. *Group II:* R. Asquith, J. C. Ballantyne, P. B. Banaji, Ailsa Bannerman, D. A. G. Brown, Amelia E. Burch, J. A. Burnett, Diana M. M. Carr, Phoebe Charlton, D. L. Davies, D. M. Dunn, P. S. Fuller, L. Goodman, S. Grossmark, J. Herbert-Burns, A. P. Hick, J. D. O'D. Lavertine, Dorothy K. Paterson, M. Radzan, S. B. Smith, P. D. Swinstead, J. Watkins-Pitchford, N. A. F. Young.

* Distinguished in medicine. † Distinguished in forensic medicine and hygiene. ‡ Distinguished in surgery. § Distinguished in obstetrics and gynaecology.

KING'S COLLEGE HOSPITAL

The Committee of Management of King's College Hospital has decided that one of the medical registrars shall be resident and has appointed R. B. Niven, B.M., B.Ch., to hold the office from January 1, 1939. To another medical registrarship has been given the name of Sir Raymond Crawford, a former dean of the medical school and senior physician to the hospital, and G. A. Kiloh, M.B., B.S., has been appointed first holder of the office. G. R. Stead, M.B., B.S., has been appointed to the Samhrooke Medical Registrarship, founded in 1866 by a lay member of the committee of management.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examination indicated:

FIRST M.B., Ch.B.—J. F. Ackroyd, E. M. Barber, C. B. Jones, M. M. Lewis, Jane Mackintosh, *Joan E. Mackworth, P. C. C. Phelps, Sybil M. Williams. *In Group II (completing examination):* J. S. Richardson. *Section I:* Ruth Appleby, Dorothy M. Ayre, D. L. Bayley, *D. C. Bodenham, Jean A. Butt, Mary Crago, J. N. P. Davies, *Marjorie O. Dunster, *J. L. Elliott, J. L. Emery, Sara M. Field-Richards, E. M. Grace, *Betty F. Hannaford, F. R. Hurford, Rosemary W. Knowles, N. E. Mellington, *C. A. St. Hill, *Jeannette Shed, *Dorothy M. Shotton,

P. R. H. Slade, A. R. Stonehill (formerly Steinberg), * Edith M. Wagstaff, * T. H. White.

* Second-class honours. † Distinction in surgery. ‡ Distinction in public health. § Distinction in forensic medicine and toxicology. ¶ Distinction in materia medica, pharmacy, pharmacology, pharmaco-therapeutics, and toxicology. * Distinction in pathology and bacteriology.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—W. Dodd, F. R. Edwards, R. L. Hartley, A. J. Helfet, L. Henry, K. Jilani, J. C. Twomey, O. Walker.

M.CH.ORTH.—S. R. Chandra, E. W. Knowles, W. R. D. Mitchell, G. C. Sen, G. M. Sleggs, J. V. Todd.

FINAL M.B., Ch.B.—Part I: W. F. Christian, J. Collins, D. W. Ellis-Jones, A. H. Hands, Mrs. C. W. L. Harries, M. P. Jones, Joan Macara, S. B. Nelles, P. P. Newman, Margaret E. Parry-Edwards, C. W. R. Roseby, Beryl M. Smith, R. H. M. Stewart, P. G. W. Sutton, Hilda Walker. *Pharmacology and General Therapeutics*: G. J. C. Brittain, W. Rotherham. Part II: S. Ellenbogen, H. Hall, J. S. Hindley, R. R. Knowles, R. J. Parry, Kathleen Pugh-Jones, H. J. Shuttleworth, H. J. H. Soubly, G. O. Thomas, Joan P. Thomson, A. G. Williams. Part III: E. J. Bowmer, H. Buckley, J. L. Chisnall, W. H. R. Cook, D. J. Doherty, O. M. Haarburger, S. Hen, A. L. T. Hutson, Iola L. T. Jones, G. Karstaedt, Helen Kay, G. L. Manson, J. M. Marchant, S. Newman, J. L. Patton, G. I. Roberts, G. R. Thorpe, G. C. Tweedie.

DIPLOMA IN TROPICAL MEDICINE.—A. S. Affnra, B. Basu, S. J. Campbell, L. J. Charles, S. K. Chatterjee, S. G. Cowper, S. Garmjana-Goonchorn, C. Haddad (recommended for Milne Medal), M. N. Hwang, B. S. Jaiswal, H. N. Lee, D. V. Oka, I. S. Parboosingh, H. R. R. E. Ramesar, S. H. Segerman, A. H. D. S. de Silva, G. C. Watt.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—Muriel I. R. ApThomas, H. B. Austin, K. Harrison, R. B. Hollos, P. N. Holmes, D. N. Kiff, Jean Mason, J. Meynell, Mary B. Oakden, Lilian P. Parry, T. B. Whitehead, E. J. Yates. Part I: Peggy Anderson, G. T. Ashley, J. G. Atherton, T. G. Barlow, E. F. Burdred, J. H. Gifford, C. Hamwee, E. Lee, D. Livshin, A. S. Ogden, W. E. Rigby, Barbara M. Statham, W. P. Sweetman.

THIRD M.B., Ch.B.—*Pathology and Bacteriology*: Eva Abrahamson, A. Ashworth, J. H. R. Barker, F. R. Brebner-Smith, T. Brittain, I. C. Campbell, G. Caplan, Rachel Claiman, Hilary J. Crewe, W. Dickson, H. Diggles, G. R. Ferguson, J. G. Ferguson, E. S. Frazer, R. J. Gampell, J. Gregory, Hilda R. Harris, H. Hassall, S. Haythornthwaite, B. L. Hoffmann, Irene E. Howorth, Margaret Jacques, O. Janus, P. W. Kippax, G. Lancaster, J. T. A. Lloyd, J. L. Muelcan, W. Mellor, Elsie L. Mettam, Catherine E. D. Nash, C. Parish, K. C. Prausnitz, T. F. Redman, F. Robinson, Margaret H. Roscoe, J. C. Seddon, G. K. Spruell, J. K. Steward, T. A. Taylor, Edith M. Thorp, A. L. Tulk, Ena M. Walmsley, Elizabeth C. S. Williams, Joyce Worthington. *Pharmacology*: E. P. Abson, R. G. Balf, J. Ball, J. K. Brown, E. A. Cachia, B. O. Dowdell, B. I. Eames, E. Feinmann, A. Glass, E. Greenwood, J. C. Greenwood, P. G. Griffiths, E. G. Hall, Frances A. Hepburn, S. H. Jackson, R. P. Jepson, H. Khazani, M. Levinson, D. C. Little, J. K. McMyn, F. S. Mooney, A. B. Morrison, T. E. Parry, S. S. Rose, Susanne M. Seligsohn, G. J. Shanklin, H. G. B. Slack, J. Thompson, Vera Waine, *A. E. Wall, F. R. Wilde, *L. Wise, B. Wolman.

* With distinction.

UNIVERSITY OF ABERDEEN

At a graduation held on December 14 the following medical degrees were conferred:

M.D.—*A. Grant, †J. A. Cardno, †H. D. Chambers, H. S. Fraser, W. R. Gauld.

M.B., Ch.B.—L. C. Allan, Margaret P. Allan, J. Anderson, S. C. Anderson, J. Caie, W. Cockburn, N. J. H. Davidson, L. G. Eddey, W. J. Finnie, F. D. Forbes, W. L. Gordon, N. L. Hulsh, Marion MacLeod, D. G. McRobbie, D. Matheson, H. K. Paterson, M. MacR. Paterson, L. G. Tulloch, J. Walker, Margaret J. Walker, Elizabeth A. White, J. Wylie.

* With honours.

† With commendation.

UNIVERSITY OF EDINBURGH

A graduation ceremonial was held in the Upper Library Hall on December 16, when the following degrees were conferred:

M.D.—D. M. Anderson, W. G. Annan (*in absentia*), †A. F. M. Barron, H. E. Collier, †I. Douglas-Wilson, F. O. Graham, †C. L.

Grant, †G. M. Greig, J. Hutton, †J. S. Lawrence, *Agnes R. Macgregor, †F. M. L. Richardson, Major, R.A.M.C., J. Ronald, A. G. H. Smart (*in absentia*).

M.B., Ch.B.—M. A. Ayoub, J. McK. Bertram, A. G. Brown, Fanny B. Chisholm (née Macintosh), P. S. Clouston, J. H. Comloquoy, S. P. Cornell, W. E. Cowie, H. D. Dobson, R. Dowie, Janet K. O. Duff, W. Finlayson, W. Forrester, W. A. Glaubman, R. M. Henderson, G. M. Jolly, A. Ketchin, E. H. Lamb, S. Lurie, R. D. McIntyre, A. MacLeod, J. W. Martin, C. M. Norman-Williams, A. A. F. Nussiebeh, B. M. Omar, J. C. Robertson, S. P. Robson, A. M. T. Runcie, W. S. Russell, Annie D. Savill, F. S. Sedgwick, Ellie Seligman, C. S. Singh, Evelyn M. Stewart, L. N. Stewart, Ida E. Wilkinson, Pnk Foo Woo, R. B. Wylde.

* Awarded gold medal for thesis. † Highly commended for thesis. ‡ Commended for thesis.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following medical degrees were conferred on December 3:

M.Ch.—R. L. Forsyth, R. G. Taylor.

M.B., B.Ch., B.A.O.—M. E. C. Balmer, Miriam A. Becket, J. W. Boland, R. S. MacL. Cooke, H. R. T. Devlin, D. B. George, Emily E. E. Hill, J. R. Mahon, J. L. Mans, D. E. Meares, F. G. Millar, J. E. Milne (formerly Murphy), J. R. Murdoch, F. W. Parke, W. A. J. Pike, Elizabeth M. Rees, Elizabeth L. J. Ryan, Kathleen E. A. Smith, D. K. Stewart, J. G. Waugh, S. L. Wray.

L.M.D., L.Ch., and L.A.O.—M. D. M. Bergin.

The following candidates have been approved at the examinations indicated:

FINAL MEDICAL EXAMINATION.—Part I, *Materia Medica and Therapeutics and Pathology and Bacteriology*: †F. G. M. Ross, †C. P. Clancy-Gore, †Maureen C. Johnston, †W. E. O'C. Powell, R. M. Halahan, S. O. O. Franklin, M. D. Leitch, M. Steinberg, L. C. Jacobson, Lois J. Macaulay, H. FitzGibbon, Olive S. H. Devlin, J. Nash, F. J. Qually, E. G. R. Butler, H. B. C. Houston, C. F. Ford, F. N. C. Levy, S. D. Reid. *In completion*: Margaret Sutcliffe. Part II, M.B.: †J. G. Waugh, †W. Sandford, †J. R. Murdock, †L. S. Levinson, Sylvia M. FitzGerald, M. Herman, Elizabeth L. J. Ryan, Miriam A. Becket, Rosaleen de C. McCormick, W. A. J. Pike, F. G. Millar, W. B. Welply, W. Jones, E. R. F. Mellon, J. W. Boland, F. R. T. Hollins, J. L. Mans, Mary A. Conyngham, D. A. Huggard, Kathleen E. A. Smith, E. R. Coetzee. B.Ch.: †Emily E. E. Hill, †S. L. Wray, †J. R. Mahon, Miriam A. Becket, F. P. O'Sullivan, J. W. Boland, Elizabeth M. Rees, Kathleen E. A. Smith, M. E. C. Balmer, R. S. MacL. Cooke, H. R. T. Devlin, D. B. George, D. K. Stewart, F. G. Millar, J. L. Mans, J. E. Milne, D. E. Meares, F. W. Parke, M. D. M. Bergin. B.A.O.: *M. O'C. Drury, *R. S. W. Baker, †C. J. Du Preez, †E. G. Hobart, †G. S. Sheill, D. L. Harbinson, S. F. H. Haughton, E. N. O. Sodeinde, G. A. Anderson, C. H. Rutherford, M. E. Tapissier, J. P. Gore-Grimes, E. F. Keating, W. M. Winn, Sheila Kenny, Patricia D. Conneannon, D. St. B. F. Nunan, Kathleen E. A. Smith, R. Brass, B. Serebro, T. Shier, F. P. O'Sullivan, R. J. Balfe, D. G. Harrison, J. R. A. Martin.

M.D.—R. Bowesman.

* First-class honours.

† Second-class honours.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—C. V. Arthur, J. A. Bailey, D. L. P. De Courey, J. Fergusson, N. A. Jevons, H. Shepherd, W. Simpson, J. W. Weston, C. E. Winterstein.

MEDICINE.—H. J. S. Coldham, R. M. Corker, H. L. Francis, J. B. Gurney Smith, J. A. L. Leeming, R. P. Parkinson, T. G. Viljoen, M. Whitehead.

FORENSIC MEDICINE.—H. J. S. Coldham, R. M. Corker, H. L. Francis, J. B. Gurney Smith, J. A. L. Leeming, R. P. Parkinson, T. G. Viljoen, M. Whitehead.

MIDWIFERY.—H. J. S. Coldham, M. Becker, M. M. El Garrahy, F. W. Ford, A. J. Fraser Simson, A. Jones, A. B. Taylor.

The diploma of the Society has been granted to M. Becker, R. M. Corker, D. L. P. De Courey, J. Fergusson, H. L. Francis, N. A. Jevons, R. P. Parkinson, T. G. Viljoen, and J. W. Weston.

BRITISH ASSOCIATION OF RADIOLOGISTS

At the recent examination for the Fellowship of the Association, the following were successful:

*J. E. Bannen, M.B., Ch.B., D.M.R.E., *T. P. Eustace, M.D., D.M.R.E., †P. R. Goodfellow, M.B., B.Ch., D.M.R.E., *S. Nowell, M.B., Ch.B., D.M.R.E., *R. G. Reid, M.B., Ch.B., D.M.R.E.

* Honours in radiodiagnosis. † Honours in radiotherapeutics.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on December 16, with Mr. W. J. Stuart, President, in the chair, the following candidates, having passed the requisite examinations, were admitted Fellows:

J. E. Andrew, M. Arnold, N. B. Bette, H. N. Bhatt, W. Blackwood, C. Bawesman, D. P. Burkett, R. J. Coto, E. J. Crawford, I. W. Davidson, K. S. Fitch, R. J. Fleming, I. T. Fraser, L. D. B. Frost, J. C. Gough, T. L. Gordon, P. R. Greaves, A. H. Hall, M. E. S. Harrison, S. H. Harrison, J. Kiely, M. V. Kramer, S. L. A. Manuwa, I. G. MacGregor, A. McKenzie, J. C. Nicholson, H. Park, H. Poston, J. F. Riley, W. Simpson, A. J. Slesor, A. L. Som, J. R. St. G. Stead, W. J. Virgin, R. H. H. Williams.

ROYAL AUSTRALASIAN COLLEGE OF PHYSICIANS

On December 15 the Royal Australasian College of Physicians was inaugurated in the Great Hall of Sydney University. The Governor of New South Wales, Lord Wakehurst, attended the ceremony and read a message from the King wishing the College all success. The Royal College of Physicians of London was represented by Dr. H. Morley Fletcher, formerly Senior Censor, who presented an address from the old College to the new, which was printed in the *British Medical Journal* of December 10 (p. 1218). The College was incorporated on April 1, 1938, under the Companies Act of the State of New South Wales as a company limited by guarantee and not having a share capital. The registered office is in Macquarie Street, Sydney. The first President is Sir Charles B. Blackburn (Sydney); the vice-presidents are Dr. C. T. Champion de Crespigny (Adelaide), Professor D. W. Carmalt Jones (Dunedin, N.Z.), and Dr. S. V. Sewell (Melbourne); the censor-in-chief is Dr. S. O. Cowen (Melbourne); the hon. secretary Dr. Allan S. Walker (Sydney), and the hon. treasurer Dr. Stewart Arthur Smith (Sydney). The Foundation Fellows number 247 and the members 39.

Medical Notes in Parliament

The business of the House of Lords this week included the third readings of the Marriage (Scotland) Bill and the Housing (Financial Provisions) (Scotland) Bill.

The House of Commons this week discussed foreign policy, the National Register, and the redistribution of population before adjourning till January 31, when the House will probably go into committee on the Cancer Bill.

During the dinner given by present and past members of the Parliamentary Medical Committee to Dr. Elliot at the House of Commons on December 14, Dr. Elliot recalled that the Committee was founded by Sir Watson Cheyne in 1919 and that he himself had been its honorary secretary from 1920 to 1922, when he was succeeded by Sir Francis Fremantle. Speeches were also made by Sir Francis Fremantle—in the chair—Sir Auckland Geddes, Dr. Somerville Hastings, Dr. O'Donovan, Sir John Worthington, Sir Richard Luce, Dr. Drummond Shiels, and Dr. A. B. Howitt. Lord Dawson was unable to attend owing to indisposition.

Progress of Bills

The Public Health (Coal Mines Refuse) Bill was reported on December 8 from a Standing Committee of the House of Commons.

The Custody of Children (Scotland) Bill and the Pensions Acts (Amendment) Bill were read a second time by the House of Commons on December 10.

On December 15 the House of Lords passed the Expiring Laws Bill.

Dentists' Annual Registration Fee

On December 5 Mr. HOPKIN asked the Minister of Health if his attention had been drawn to the fact that dentists qualifying after 1921 had to pay an annual registration fee of about £4, whereas other dentists had to pay no annual fee; and if, in view of the dissatisfaction among dentists, he would inquire into the whole question. Earl WINTERTON, who replied, said that the Dentists Act, 1921, provided that the payment of the annual fee in question might be required only in the case of dentists registered after the commencement of the Act. This provision, which preserved the rights of those practising dentistry before the Act was passed, gave effect to a recommendation of the Interdepartmental Committee on the Dentists Act, 1878. He was not aware that the provision had caused any general dissatisfaction in the dental profession, and he did not consider that further inquiry was called for.

Workmen's Compensation Bill

In the House of Commons on December 10 the Workmen's Compensation Acts (1925 to 1938) Bill was rejected on second reading. This Bill, introduced by Miss Irene Ward, proposed to deal with compensation claims for miners' nystagmus. Miss Ward explained that it was designed to implement the report of the Stewart Commission. M.P.s for mining constituencies opposed the Bill because they were not satisfied with the system of diagnosis which it proposed. Mr. W. J. STUART said nystagmus was often not discernible to a medical man when the miner was above ground. Mr. GEOFFREY LLOYD said there was not now much increase in miners' nystagmus. He referred to unsatisfactory arrangements for medical certification.

A.R.P. at Mental Hospitals

On December 13 Mr. BERNAYS, replying to Mr. Sorensen, said that the Minister of Health hoped to issue very shortly a memorandum on the air raid precautions which should be carried out at hospitals, including mental hospitals, in the more vulnerable areas. Information regarding precautions actually being carried out had been utilized in the preparation of the memorandum. The Government was prepared to assist in approved cases towards expenditure on precautions at hospitals, including mental hospitals, which were included in the emergency hospital schemes. No estimate of the total expenditure involved in protecting mental hospitals could be given at present, as the appropriate measures varied widely according to local conditions.

Board of Control for Scotland

In moving the second reading of the Reorganization of Offices (Scotland) Bill in the House of Commons on December 13, Colonel COLVILLE said that the proposals were based on the report of the Committee on Scottish Administration, appointed at the end of 1936. The committee had considered the question of the reorganization of the General Board of Control. It was represented to them by certain witnesses that the intimate relations between physical and mental health made it desirable to abolish the Board altogether and to transfer its functions to the Department of Health. The committee, however, decided that there were special reasons—in particular the necessity for having a separate body with independent and quasi-judicial functions to protect the interests of the insane—which made it desirable to retain the Board. The Government accepted this recommendation. At the same time, they felt that the views expressed by the committee as to the need for strengthening the Board's staff and associating it more closely with the Department of Health were wise.

The existing Board was therefore being reconstituted. It would consist of a paid wholetime chairman, who would be an officer of the Department of Health holding the rank of assistant secretary; the two existing paid medical commissioners; a part-time paid legal commissioner; a representative

of the Scottish Education Office; and two unpaid members representing the general public. The committee took the evidence of several medical men on the question. They had the Scottish Division of the Royal Medico-Psychological Association before them in the person of Professor Henderson and Dr. McAlister. They also had the Board of Control for England and Wales, and heard Sir Hubert Bond as representing the medical interests, and also Dr. Thomson of the Board of Control for Scotland. On balance the Government decided that the advice expressed as to the protection of the interests of the insane by a quasi-judicial body was good, and they had therefore adopted it. It was intended that the functions of the Secretary of State relating to lunacy and mental deficiency should, when the new system became operative, be discharged through the Department of Health, and not through the Scottish Office as at present.

The Bill was read a second time by 157 votes to 99, and committed to a Standing Committee.

Gold Coast Medical Service

In reply to Mr. Cecil Wilson, Mr. MALCOLM MACDONALD said on December 14 that the scale of salary for a European medical officer in the Gold Coast was £660 a year for three years, then £690 a year rising by annual increments of £30 to £840 a year, then, subject to passing an efficiency bar, £880 a year rising by annual increments of £40 to £1,000 a year. The period of probation was three years, and free quarters were provided.

The scale of salary for an African medical officer in the Gold Coast was £500 a year rising by annual increments of £25 to £600 a year, thence, subject to passing an efficiency bar, rising by annual increments of £30 to £720 a year. The period of probation was three years, and free quarters were not provided. While awaiting probationary appointment an African (suitably qualified) might be employed as a junior medical officer in one of the larger hospitals of the Gold Coast for a period of preliminary training, during which he was granted salary at the rate of £400 a year.

At present the higher posts in the medical department of the Gold Coast were normally filled by European officers belonging to the Colonial Medical Service. No appointments were actually reserved for European officers, and in the medical as in the other branches of the Service African officers were fully eligible to be considered on their merits for promotion to any appointments for which they may be qualified.

Bill to Control Sale of Contraceptives

The second reading of the Contraceptives (Regulation) Bill was moved on December 16 by Mr. O. E. SIMMONDS. He said the decline by 54 per cent. in the birth rate of England and Wales between 1880 and 1930 proved that a large section of the community believed it had a moral right to birth control. The Bill dealt not with public morality but with public decency, and circumscribed some of the offences against public opinion committed by those who traded in contraceptives. Such aggressive practices included the nauseating display in shop windows, sale from slot machines, and distribution of alluring literature. Most young people in their 'teens had moral fibre to resist the temptation of this flagrant commercialism, but it was known to have the saddest results in many cases. Youngsters who replied to advertisements by certain physical culture experts received later batches of contraceptive literature. It was reported from an industrial area that factory girls procured contraceptive devices from slot machines and carried them in their handbags. Mr. Simmonds said a similar Bill had previously been introduced in the House of Lords by Lord Dawson and in the Commons by Mr. R. J. Russell. Clause 1 of the present Bill prohibited the display of contraceptives in or outside any shop in a manner visible to persons outside the shop. It also prohibited the sale or hawking of contraceptives in streets and public places or by automatic machines placed to be used by persons in streets or public places. A paragraph prohibited the unsolicited dispatch to persons under 18 years of contraceptives or of

circulars and advertisements dealing with them. The Bill did not prevent anyone desiring to purchase contraceptives from having reasonable opportunity of doing so, and it did not deal with the distribution of literature through societies. It did not raise the question of aphrodisiacs or sexual stimulants, nor did it touch abortifacient devices. A committee on abortion was now sitting. If a bottle of olive oil were placed in a window and marked "Olive oil for contraceptive purposes," the vendor would be liable under the Bill, but not if there were no reference to contraception. In industrial areas the problem of the sale of contraceptives was serious. Many varieties of contraceptives could be purchased from slot machines in Birmingham.

Mr. SALT seconded the motion.

Sir WILLIAM WAYLAND moved an amendment declaring that the whole subject of improper commercial exploitation of contraceptive, abortifacient, and aphrodisiac devices should be dealt with by a Bill after publication of the Report of the Departmental Committee on Abortion. Sir William said the reduction in venereal diseases was largely due to the use of contraceptives. Instead of trying to prevent them being sold Parliament should try to teach young people to use them properly.

Sir FRANCIS FREMANTLE moved the closure, but this was refused by the Speaker, and the second reading discussion was adjourned till February 10. Further progress with the Bill this session is improbable.

Children for Adoption: Medical Certificates

Miss HORSBRUGH moved, on December 16, the second reading of the Adoption of Children Bill. She said it was founded on the recommendations of the Departmental Committee, set up by Sir John Simon when Home Secretary, to study the difficulties and the methods pursued in child adoption, particularly when adoptions were arranged by associations or groups of people. She had been chairman of that committee. Legislation passed for England in 1926 and for Scotland in 1930 failed to cover the cases where adopters did not go to the courts for adoption orders and omitted to deal with the third party who arranged the adoption. The Bill would deal with abuses or neglect in these cases. Clause 4 (c) dealt with inquiries to be made if adoption were to be successful, and expressed the necessity for obtaining a certificate concerning the child's health. The best adoption societies insisted on having a doctor's certificate, and several societies insisted on a Wassermann test either in the case of the child or the mother, but other societies did not insist on this. Children with venereal disease might be received into a hostel with other children and sent out for adoption as healthy children. Therefore if adoption societies were to be registered this regulation about medical certificates should be insisted upon.

Mr. GEOFFREY LLOYD said the opinion of the Government was that the Bill was very useful.

The Bill was read a second time and sent to a Standing Committee.

Nurses' Emergency Register.—On December 12 Dr. ELLIOT informed Mr. R. Duckworth that one of the main objects of the emergency register of nurses was to secure the services in a national emergency of women with nursing experience no longer practising, who would be a valuable reinforcement to nurses already attached to hospitals and other institutions.

Silicosis among Slate Miners.—Mr. GEOFFREY LLOYD stated on December 15 that an expert medical inquiry carried out a few years ago revealed no evidence of silicosis among slate quarrymen, but the Home Secretary was aware of some evidence pointing to the occurrence of silicosis among slate miners working underground in the Festiniog area.

Milk in Schools.—On March 31, 1938, there were 5,035,506 children on the registers of the public elementary schools in England and Wales. Of these, 2,235,278 were receiving milk on payment at the reduced rate under the milk-in-schools scheme and 457,062 were receiving free milk. Corresponding figures for Scotland are: number of children on the registers

of primary schools, 613,984; number of children receiving milk on payment at the reduced rate under the milk-in-schools scheme, 237,581; children receiving free milk, 62,472. In forty-eight areas in England and Wales, for the most part small, the local education authorities, of which four are in Lancashire, do not exercise their power of providing free milk. In eight of these areas free solid meals are provided.

Approved Societies Benefits.—Dr. Elliot cannot give any undertaking about the introduction of amending legislation to bring uniformity in cash benefits to all members of approved societies and in make dental and ophthalmic benefits available to all these members. He and Mr. Cnville recently received a deputation on this subject, which Dr. Elliot describes as highly controversial.

Safety in Mines.—The report of the Royal Commission on Safety in Mines has been signed and submitted to the King. Captain Crookshank hopes that copies will be available for members of the House of Commons in about a fortnight.

Bacterial Content of Pasteurized Milk.—The Milk (Special Designations) Order, 1936, prescribes a maximum bacterial content for pasteurized milk before delivery to the consumer, and Dr. Elliot is advised that the method of counting laid down by the Order is reasonably suitable. It is for the licensing authority under the Order to take steps to secure compliance with the prescribed standard.

Extent of Overcrowding.—The latest reports of the medical officers of health place the number of overcrowded houses at the end of 1937 at 265,000—a reduction of about 77,000 on the figure of the original survey of 1935-6.

Notes in Brief

The Interdepartmental Committee on the Nursing Services is likely to submit an interim report in the very near future.

A scheme for the centralization of health services in Barbados has been drafted by the Board of Health and awaits consideration by the Legislature.

Medical News

A meeting of the Society for the Study of Inebriety will be held at 11, Chandos Street, W., on Tuesday, January 10, at 4 p.m., when Commissioner David C. Lamb, chief of the Intelligence Office of the Salvation Army, will open a discussion on "Inebriety: Some Aspects of the Problem."

Immediately preceding the annual congress of the Ophthalmological Society of the United Kingdom on April 20, 1939, the following meetings will be held at the Royal Society of Medicine, 1, Wimpole Street, London, W.: International Association for the Prevention of Blindness (address, 66, Boulevard Saint-Michel, Paris, VI), on Wednesday, April 19, at 2 p.m., "The Application of the Cr  d   Method for the Prevention of Ophthalmia Neonatorum in Various Countries." The speakers will be Dr. Sinclair (Edinburgh); Professors Terrien (Paris), V. Szily (Munich), Maggioro (Genoa), Vasquez Barri  re (Montevideo); Dr. Wilson (Cairo); Mr. J. D. M. Cardell (London), Dr. C. Herens (New York). International Organization against Trachoma (address, 33, Welbeck Street, London, W.1), April 19, at 4.30 p.m., "The Incidence and Clinical Type of Trachoma met with in Europe and North and South America—that is, in countries which are commonly considered to be non-trachomatous." The speakers will be Dr. Lavery (Dublin), Dr. Harry Gradle (Chicago), Mr. Arnold Sorsby (London). Subsequently there will be a short discussion on the treatment of trachoma by sulphanilamide and its congeners. Members of the congress are invited to attend these meetings, and ophthalmologists from abroad are invited to attend all meetings of the congress.

The twenty-ninth annual exhibition of scientific instruments and apparatus, arranged by the Physical Society, will be held at the Imperial College of Science and Technology, Imperial Institute Road, South Kensington, as follows: January 3, 2.30 p.m. to 9 p.m.; January 4, 4 p.m. to 9 p.m.; January 5, 2.30 p.m. to 9 p.m. The leading manufacturers of scientific instruments will be exhibiting their latest products in the Trade Section. The Research and Educational Section will contain contributions from research laboratories, and experiments of educational interest. A discourse will be delivered on January 3, at 7.45 p.m., by Dr. J. D. Cockcroft, on "The Cyclotron and its Applications." Admission to the exhibition is by ticket only, obtainable from the Exhibition Secretary, 1, Lowther Gardens, Exhibition Road, S.W.7.

In connexion with the fortieth anniversary of the discovery of radium a special wireless programme was relayed to America from Paris on November 27, in which there took part Senator Justin Godard, president of the International Union against Cancer, Dr. Francis Carter Wood, director of Columbia University's Institute of Cancer Research, and Dr. J. E. Gendreau, director of the Radium Institute at Montreal. The last speaker recalled how on her visit to America in 1921 Madame Curie had found in a practical country enthusiastic idealism and a friendly sympathy which gave her renewed inspiration and courage. The 1939 meeting of the Union is to be held at Atlantic City, New Jersey.

The Minister of Health on December 9 received a deputation consisting of representatives of the Oxford and District Joint Hospitals Board, the British Medical Association, and the Emergency Committee of Oxford and District. The deputation put before the Minister a statement as to their experience of the emergency provisions before and during the recent crisis. The division of responsibility between the central and local officers, the areas at present covered by hospital officers, and the arrangements decided on between the Ministry of Health and the Service Departments for the best use of the hospital accommodation of the country were among the topics discussed. The Minister promised to bear in mind the suggestions of the deputation with regard to the organization of their district for the future.

The postgraduate news in our *Supplement* contains an announcement of clinico-pathological demonstrations by the staff of Westminster Hospital on Tuesdays, at 5 p.m., beginning on January 3 and continuing at fortnightly intervals.

Lord Nuffield has given a cheque for £31,383 to the Wingfield Morris Orthopaedic Hospital, Oxford, for capital expenditure on buildings and equipment. This brings his gifts to the hospital up to £140,000. His benefactions in the cause of orthopaedic surgery in Great Britain, Australia, New Zealand, and South Africa now amount to approximately £500,000.

The authority for awarding the Nobel prize in medicine, the College of Teachers of the Caroline Institute, Stockholm, has recently announced that no prize for medicine will be awarded in respect of the year 1938.

Dr. Ellice M. Alger, Professor of Ophthalmology at the New York Post-Graduate Medical School, on December 1 received the Leslie Dana Gold Medal "for outstanding achievements in the prevention of blindness and the conservation of vision" at the annual meeting in New York City of the National Society for the Prevention of Blindness.

Twenty-three Jewish professors from twelve Italian universities have been dismissed, including Ugo Lombroso (physiology), Albert Ascoli (morbid anatomy), Mario Donati (surgery), Carlo Foa (physiology), and Maurizio Ascoli (internal medicine).

Mr. Thomas E. A. Stowell, F.R.C.S., has been re-elected to the Council of the Industrial Welfare Society, of whose Advisory Medical Committee he is the chairman.

Professor Raffaelli Paolucci has been elected successor to Professor Roberto Alessandri in the chair of clinical surgery in the Faculty of Medicine at Rome.

Professor A. Staniceff, the eminent Bulgarian surgeon, has been elected rector of Sofia University.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 10, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 126 great towns (125 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases : a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

† After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.

‡ Deaths from puerperal sepsis.

EPIDEMIOLOGICAL NOTES

Principal Infectious Diseases in England and Wales
during November, 1938

In the five weeks ending December 3, 1938, 9,885 cases of scarlet fever, 7,467 cases of diphtheria, 3,451 cases of primary pneumonia, and 133 cases of enteric fever were notified in England and Wales. The notifications of these were respectively 76 per cent., 108 per cent., 76 per cent., and 79 per cent. of the expected numbers (deduced from the median values of the corresponding weeks of the years 1929-37).

Enteric Fever 1937-8

An increase in typhoid morbidity was observed in 1937, in comparison with the previous year, in the United States of America and Japan and in most European countries; the only countries in which a decline was recorded were Norway, Bulgaria, Yugoslavia, and England. In this country, in spite of the increase in November (chiefly the Croydon epidemic), the number of cases recorded in 1937 was only 84 per cent. of the number for 1936. The available data for typhoid morbidity in Europe show little change compared with 1936; the highest rates were recorded in Portugal (16.5 per 100,000 population, as against 14.3 in 1936), Malta (10.3), and Hungary (9.5, as compared with 10.1). Then came Czechoslovakia (6.3 against 6.0), Bulgaria (5.8), Lithuania (5.5), Rumania (4.3), Turkey (3.8), and Yugoslavia (3.5 per 100,000). In 1938 a decline in the number of cases was observed in England, Germany, France, Czechoslovakia, Poland, the Netherlands, and the Scandinavian countries. Despite the observed decline in morbidity in recent years the seasonal distribution, which differs somewhat from country to country but is generally greatest in the second and third quarters of the year, remains unchanged. The incidence of the disease in 1938 was below the median value for the years 1927-37 in England, France, and Poland, and below the median for the period 1933-37 in Hungary.

During the week under review the incidence of enteric fever in England and Wales and in London fell from 29 to 24 and 8 to 5 respectively. The centres chiefly affected were: Lancashire 5 (Liverpool 4, Blackpool 1); London 5 (Shoreditch 2, Battersea, Islington, and Lambeth 1 each); Essex 2 (Dagenham, Romford); Yorkshire West Riding 2 (Sheffield, Holmfirth). No more cases of typhoid fever have been notified in the Shoreditch outbreak since last week, but a third death has been reported.

Acute Poliomyelitis*

There was an appreciable drop in the notifications of acute poliomyelitis in England and Wales and in London during the week—27 (37) and 2 (9) respectively. The chief counties affected were: Southampton 3 (Bournemouth, Southampton, Eastleigh); Essex 2 (Colchester 2); Glamorgan 2 (Cardiff 2); Kent 2 (Bromley, Chislehurst and Sidcup); Lancashire 2 (Barrow-in-Furness, Westhoughton); London 2 (Deptford, Lewisham); Middlesex 2 (Harrow, Twickenham); Surrey 2 (Guildford, Kingston-on-Thames). According to a statement in the Press 2 cases of poliomyelitis occurred at Wellington College and parents were notified that their sons could return home immediately.

Infectious Diseases in China (Canton)

A recent report states that despite the constant influx of refugees and the continued migration of large numbers of persons there have been no serious epidemics during the past year and the general health of the people has maintained an average standard so far as infectious diseases are concerned.

Small-pox.—The epidemic which began in December, 1937, lasted until April, 1938. No accurate figures are available, but a number of cases is estimated at 1,000 to 2,000. There

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

was a high proportion of cases of haemorrhagic small-pox and of purpura variolosa. Work at the Sai Chuen military academy indicates that assistance in the diagnosis of difficult cases at the beginning of an epidemic may be obtained by sternal puncture, the view being held there that in small-pox there is in the bone marrow an increase of the plasma and reticulum cells and of lymphocytes.

Malaria.—Only a few cases occurred in Canton, and the disease never assumed epidemic proportions there. There was one death in a European. Serious epidemics occurred elsewhere in the province, especially in the eastern area, in the Swatow area, and in Hong Kong and Macao.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitology Western, London.

SECRETARY, Medisera Western, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone 2436) Edinburgh, and of the Office of the Cumann Doctúirí na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Baicillus, Dublin; telephone 62550 Dublin).

QUERIES AND ANSWERS

Flatulence on a Milk Diet

"E. S." asks for information concerning the prevention of flatulence with patients on a milk diet.

* Excessive gas occurring in the alimentary tract of a patient on a milk diet is either swallowed air or gas formed by fermentation. Actually milk tends to decrease rather than increase intestinal fermentation, and therefore the more likely cause of flatulence is the excessive swallowing of air. This may be prevented by giving the milk in semi-solid or solid form. Milk jelly, junket, and cornflour shapes might be tried. There is an excellent chapter on milk in the latest edition of Hutchison and Mottram's *Food and the Principles of Dietetics* (p. 136). If fermentation is suspected as a cause one of the special milks such as sour milk or buttermilk might be tried.

Wasp Stings

Dr. C. STRICKLAND, Professor of Medical Entomology, Calcutta School of Tropical Medicine, writes with reference to "A. H. D.'s" query on wasp stings (*Journal*, October 1, p. 727): I would suggest he look up L. I. B. Braun in *South African Medical Record*, September 26, 1925, vol. 23, No. 18, p. 408, for Notes on Desensitization of a Patient Hypersensitive to Bee Stings. Of course a bee is not a wasp, but there you are!

Income Tax

Tax Deducted from Annuity

"J. G." pays his mother £100 a year under a deed for a period of seven years. He deducts tax from the payments and the amount so deducted is repaid to the mother when she

reclaims it. He asks, "Do I have to repay to the Inland Revenue the amount of tax I have deducted?"

** No; the effect of the deed is to convert £100 of his income into the legal income of his mother. She is entitled to have the tax repaid to her, and there the matter ends so far as "J. G." is concerned.

Repayment of Loan

"A. J." borrowed £2,000 to buy a share in a partnership on terms requiring him to pay back £250 per annum. Is there any way in which he can get relief on this £250?

** No; the payments represent savings out of income, are capital in their nature, and do not affect income tax liability.

LETTERS, NOTES, ETC.

Treatment of Cracked or Sore Nipples

Dr. J. WALKER (Bootle, Liverpool) writes: In an experience of over fifty years in general practice I have found nothing so effectual in promoting rapid healing of cracked or sore nipples as a very old, and apparently almost forgotten, device known as "Wansbrough's metallic nipple shield." The action of the milk on the shield produces lactate of lead; of course, the nipple is carefully cleansed after removal of the shield.

Sulphonamide in Acute Cystitis

Dr. A. FREITAG (South Norwood) writes: I think the following case might be interesting from the point of view of the rapidity of the response to sulphonamide therapy. A married woman aged 38 was operated on, on October 21, for a chronic prepyloric ulcer. On October 28, while in hospital, she developed slight dysuria and frequency of micturition. She was sent home on November 7. I saw her on November 9, when her frequency of micturition and dysuria were a little more troublesome. On November 11 she developed rigors; her temperature was 103° F., her pulse rate 120, and her urine contained *B. coli*. The dysuria and frequency were very distressing. I put her on sulphonamide, 1 gramme every four hours, followed by copious fluids. On November 12 her temperature was 100° F., her pulse rate 90, and she felt better as regards her urinary symptoms. On November 13 her temperature was 98.6°, her pulse rate 84, and the urinary symptoms had almost completely disappeared. The dosage of sulphonamide was reduced to 0.5 gramme three times a day for another two days, and then stopped. She has had no recurrence since and has felt perfectly well. The interesting point is that within twenty-four hours of the first administration of sulphonamide the patient improved dramatically without any other treatment whatsoever.

Karl Sudhoff

Dr. WALTER R. BETT writes: In these days of political bewilderment, when even the ideals of scientific fellowship are challenged and in jeopardy, the brilliant and monumental researches of Karl Sudhoff continue to bear testimony to his daily renewed and daily vindicated consciousness of a common intellectual heritage. To many men in many lands his friendship was a sense of comradeship in work that recognized no national limitations. Son of a Protestant Minister, Sudhoff was born at Frankfort-on-Main on November 26, 1853. At the age of 25 he started general medical practice at Bergen, near his native city, four years later moving to Hochdahl, near Düsseldorf. His scanty leisure was divided between gardening and medical history. When he was 52 years old it so happened that the widow of the Viennese medical historian, Theodor Puschmann, left her entire fortune to the University of Leipzig to promote medico-historical research. Sudhoff, who had acquired a taste for this subject in his student days and who was entirely self-taught, in 1905 accepted the chair on condition that an institute was built for him. A born researcher, with a sound training in the ancient languages, unquenchable enthusiasm, and an excellent memory, for nearly twenty years he travelled far and wide combing public and private libraries, archives, and museums for rare and unprinted medical manuscripts and illustrations, which he photographed, collated, and edited. No one ever saw him tired. Fond of the society of young people, his was a happy, imperious, temperamental nature. While as a lecturer he could be exceedingly dull, in conversation he was always

interesting and even inspiring. A voluminous and charming correspondent, his handwriting even in his old age was clear, bold, and artistic. Of his original contributions to medical history, his writings on the School of Salerno, on leprosy, syphilis, and plague, and particularly on Paracelsus, whom he may be said to have rediscovered, are exhaustive and of permanent value. While the *Sudhoff Archiv für die Geschichte der Medizin* and the Professor Karl Sudhoff-Strasse in Hochdahl tangibly perpetuate his name, his memory will continue to animate and inspire medical historians of the civilized world for many generations to come.

An American Country Doctor's Notebook

Dr. JOHN S. MEIGHAN writes from Glasgow: Please allow me heartily to commend to those of your readers who do not know it Dr. Wm. N. Macartney's *Fifty Years a Country Doctor* (U.S.A.—British publisher, Geoffrey Bles). In addition to many interesting experiences the reader will find many valuable tips and wrinkles of all kinds, some of them admittedly heterodox, but perhaps none the worse for all that. It is sad, however, to find Dr. Macartney recommending linsed poultices for boils, and his statement, "A boil is always ready for incision from the time it starts," is sadder. Surely modern experience is agreed that the less boils are interfered with locally the better, while boils in the facial area should be left severely alone. Dr. Macartney is typical of what might now be called the "old" family doctor, and is just the sort of man one would like to see at one's own bedside, in the first instance at least, if one were seriously ill. He himself, however, does not believe that the day of the G.P. is over. "From two-thirds to three-fourths of our population are still treated by their family physicians," he says, and "The species is a long way from extinction; they are a hardy breed and will survive." The British reader of the book should bear in mind that, to Dr. Macartney, Bombay is not the "Gateway of India," but a small town in the north of New York State. The book is, unfortunately marred by numerous printer's errors (there seems to be an epidemic at present in London of what I might call "proof-readers' carelessness"), and by an extraordinary oversight page 347 appears between pages 345 and 346.

Tuberculosis Christmas Seals

For thirty-two years the double-barred red cross has appeared on Christmas seals, issued at first by the American National Red Cross, and since 1920 by the National Tuberculosis Association. This year's design depicts two children standing by a curtained window and watching their mother place a lighted candle on the sill. The three figures are dressed in mid-Victorian attire, and the predominant colours are red and green. The seals are issued in sheets of one hundred stamps, ninety-six being the regular seals, while the four corner ones are portraits of Laennec, Koch, Edward Livingston Trudeau, who in 1884 founded the first American open-air sanatorium for early tuberculosis, and of Einar Holboll, a Copenhagen post-office clerk, who in 1904 suggested the use of Christmas seals to brighten letters and greetings and to raise funds towards building a tuberculosis hospital.

pH for the G.P.

Those who would like to know a little more about the mysteries of pH can obtain some useful information from a booklet produced by the British Drug Houses, Graham Street, London, N.1, entitled *pH Values: What They Are and How to Determine Them*. This is the fifth edition of the booklet, and now consists of thirty-two pages which include among other things a chart of indicators and hydrogen-ion concentration data. A copy will be sent free to any practitioner who applies to the above address.

Wanted—Osteology Sets

Brigadier T. C. MUDIE, D.S.O., Secretary of the Scottish Branch, British Red Cross Society, writes from 206, Bath Street, Glasgow, C.2: May we ask the courtesy of your columns to appeal to any Scottish doctors who have osteology sets they no longer require to send them to us for the use of first-aid classes? We are at present organizing an exceptional number of such classes both for V.A.D.s and for A.R.P. volunteers, and would be most grateful for any sets for instructional purposes.

 Chemistry of Vitamin C. C. King.—p. 1462.
 Local Urinary Antiseptics. H. Walther.—p. 1465.

Psycho-analysis and Alcohol Addiction.—Knight has spent about 2,000 hours analysing twenty male addicts. Sanatorium treatment and psycho-analysis combined for periods of one and a half to four years appear to offer some hope for alcoholic addicts. The waning urge to recover of the patient himself and interference on the part of relatives are among the many difficulties encountered in practice.

Sulphanilamide and Human Milk.—In order to find out whether sulphanilamide is excreted in breast milk, and, if so, in what amounts and what effect it has on the nursing baby, Stewart and Pratt studied twenty-eight normal convalescent mothers. Estimations of the milk and blood of the mothers showed that the drug was excreted in both; it was also found in the blood and urine of the babies, but it is believed that the baby cannot obtain an adequate therapeutic dose through the mother's milk when she is receiving only an average clinical dose.

 Effect of Weak Doses of Nicotine on *Lebistes reticulatus*. E. R. Schuster-Woldan.—p. 1481.

Triboulet Test.—This bichloride of mercury-acetic acid reaction has proved positive in 100 per cent. of intestinal infections. It should prove a valuable complement to bacteriological tests.

Lancet

London vol. 2 October 15, 1938

- Bacteriæmia. J. A. Ryle.—p. 867.
 *Treatment of Ankle Fractures. W. G. Campbell.—p. 872.
 Oxygen Therapy. Note on New Nasal Mask. R. V. Christie.—p. 876.
 New Chemical Contraceptive. J. R. Baker, R. M. Ranson, and J. Tynen.—p. 882.
 Cardiazol Convulsion Therapy in Non-schizophrenic Reaction States. L. C. Cook and W. Ozden.—p. 885.
 Traumatic Myositis Ossificans. W. B. R. Monteith.—p. 888.
 Polycæmia after Ulcer Treatment. C. T. van Valkenburg and G. A. Kreuzendelich von dem Borne.—p. 889.

Ankle Fractures.—Campbell adopts Ashurst and Bromer's classification of Pott's fractures. He regards "minor fractures," in which only one side of the joint is affected, as essentially stable and not requiring support. Eighteen such cases are described, treated by procaine injections without support; in no instance did displacement or non-union follow. The essential steps in diagnosing the "minor fracture" and controlling the treatment are given fully.

"Chinfortan Homburg" in Treatment of Lung Infections. K. Blanke.—p. 1493.
Treatment of Purulent Infections with Unguenta containing Tar. O. Lange.—p. 1495.

Nicotine and Cardiac Damage.—Chronic nicotine poisoning in smokers, according to Laessing, results from several factors. Constitution, age, sex, abuse of caffeine and alcohol, debility, and the amount of tobacco consumed are important. Subjective symptoms are vague but reminiscent of cardiac neuroses and angina pectoris. Palpitation, tachycardia, vertigo, headache, and faints may be complained of. There may be pain behind the sternum and alternating feelings of cold and heat. Objective symptoms include bradycardia and tachycardia, changes in rhythm, and extrasystoles. The blood pressure is usually lower than normal. The heart is occasionally enlarged and changes in the electrocardiogram may be observed.

*Existence of Haematopoietic Hormone Demonstrated by Production of Polycythaemia by Means of Anterior Lobe Hypophyseal Extracts. J. Flaks, I. Himmel, and A. Zotnik.—p. 1506.

Lambliasis.—Garin states that before 1936 he had tried twenty-three remedies for this condition without much success, but since Galli-Valerio of Lausanne first had the idea of using atebirin it has been tried on an extensive scale and found to be practically specific.

Polycythaemia and Hypophysis.—The authors, as a result of their experiments on rats, claim to have demonstrated the presence of a special haematopoietic hormone in the anterior lobe of the hypophysis.

Sterility is chiefly due to Chronic Gonococcal Infection. C. Bécélère and E. François.—p. 1525.
Oubaine Arnaud. C. Dimitracoff.—p. 1527.

Angina Pectoris.—Eighty "explanations" have been put forward, according to Audibert and Legré, to account for the various manifestations of angina pectoris. The authors claim, however, that they may all be reduced to one—namely, stimulation of the sensory nerve supply to the heart—that is, the cardiac plexus. There can therefore be no such thing as a "false" angina, though there may be benign or malignant forms of the disease according to the circulatory efficiency of the individual concerned.

Frequency and Evolution of Hallucinatory Syndrome in General Paralysis treated by Malaria. M. Tchernak.—p. 1179.

Chronic Alcoholism and Pellagra.—Chronic alcoholism in civilised countries is a frequent cause of hypovitaminoses—especially of B factors and of C; it may thus cause pellagra. An alcoholic patient is described in whom a bullous and erythematous eruption, stomatitis, and diarrhoea, psychotic changes, and coproporphyrinuria occurred acutely after a brief sunbath, thus simulating Günther's acute porphyria-pathia. The condition cleared up rapidly under treatment by nicotinic acid and a diet rich in vitamin B. The part played by perverted porphyrin metabolism and photosensitization in pellagra is discussed.

Insulin in Non-schizophrenic Psychic Disturbances.—The effect of insulin in schizophrenia is not specific. Extensive trials in schizoid psychopaths and neurotics have shown insulin treatment to be followed by increased accessibility to psychotherapy as well as by improvement in insomnia and in the physical condition; favourable psychic reactions similar to those noted in schizophrenics also follow. Deep coma need not necessarily be induced. Insulin therapy is particularly commended in toxicomaniac conditions and in climacteric psychoses, but was found harmful in hallucinations associated with Parkinsonism. It is useful in exogenous but not in endogenous depressive states.

Takata Reaction in Blood Serum (Eng.) J. Horejs—p. 408.

Amino Acids and Liver Function.—Estimation of the response to an intravenous injection of glycine gives information regarding nitrogen metabolism and hepatic function. An increase in the urea excreted in the urine after the injection is of favourable significance. The test shows results which are in tolerable agreement with other tests of hepatic function.

Takata Reaction.—The Takata reaction is a flocculation test with 0.5 per cent. mercuric chloride and 0.02 per cent. diamant fuchsin dye. It has proved useful for diagnostic purposes in liver diseases, and is therefore recommended as a routine clinical method in such cases.

Emotional Lymphocytosis in Albino Rat E. J. Farris—p. 325.

Falkner Ovary.—A detailed examination of this human ovum has been made, and photographs of representative sections and of a reconstruction in the median plane of the embryonic plate have been published. The embryonic disk measures 0.15 mm. in the longitudinal axis and is 0.29 mm. in breadth. The age is estimated to be approximately seventeen days. The primitive streak occupies about one-third of the length of the disk. A notochordal plate is present, which ends anteriorly in what is regarded as a prechordal plate. Strands of mesoderm connect the ventral pole of the yolk sac with the wall of the chorionic vesicle, and the yolk sac shows a partial division into two compartments.

Carbonate Excretion.—A simple test for alkalosis in patients with peptic ulcer under treatment with soluble carbonates is described. The reagent used is nickel sulphate. Patients who are taking sodium bicarbonate or other soluble carbonates excrete demonstrable amounts of carbonate in the urine, as shown by this test. Should alkalosis develop, the carbonate excretion is reduced or absent, but reappears on a return to a normal acid-base equilibrium.

Chemical Mediators in Aqueous Humour. J. V. Luceo and K. Lissak.—p. 271.

Oxygen Saturation of Venous Blood.—Sixty-three normal subjects in basal rest had an average oxygen saturation of the arm vein blood (antecubital fossa) of 68.2 per cent. and a range of saturation of 25 to 85 per cent.; 30 per cent. of the observations were outside the range 60 to 85 per cent., which is often stated to be the "normal limit." The saturation in normal women tends to be slightly lower and the oxygen yield to the tissues, per 100 c.cm. of blood, tends to be slightly greater than in normal men in the basal state.

Flocculation of Some Therapeutic Sera in Buffered Media. A. Bontarie and M. Roy.—p. 319.

Spirochaetosis in Algeria.—The late André Sergent describes a study of the characters and mode of transmission of *Spirochaeta hispanicum*, the cause of a severe type of relapsing fever in Spain and Northern Africa. Transmission by the dog tick *Rhipicephalus sanguineus* was demonstrated; possible reservoirs of the infection are the rat, dog, and even man. Most laboratory animals, including guinea-pigs, are susceptible to the infection. Arsenical treatment is useless and even dangerous. In the experimental disease a good curative effect was obtained with the serum of recovered animals.

Archiv für Ophthalmologie

*Influence of Ocular Poisons on Blood Picture of Rabbits. K. Hoshi.—p. 553.

Physical Chemistry of Spontaneous Retinal Detachment. Y. Sugita.—p. 561.

General Disturbances in Glaucoma.—Elaborate biochemical investigations in fifty-five patients with primary glaucoma and in a control series gave essentially negative results, except that the cholesterol content of the blood was high and the xanthoprotein reaction in the serum was almost always positive in the glaucoma patients but not in the controls. The possibility of some liver damage as a cause of primary glaucoma is discussed.

Action of Toxins on Eye.—The view, advanced on experimental evidence, that kidney extract has a selective toxic action on the retina is shown to be fallacious. Similar toxic lesions can be produced experimentally by extracts of spleen and liver.

Ocular Poisons and Blood Picture.—The injection of kidney and liver extracts and of "septojod" produces retinal degeneration in rabbits. The blood picture shows changes suggestive of haemolysis of the red blood corpuscles. The significance of these findings in relationship to the increase of basophil erythrocytes in renal retinitis is discussed.

Archives of Pathology

Chicago vol. 25 September, 1938

- *Giant Follicular Lymphadenopathy with or without Splenomegaly: Its Transformation into Polymorphous Cell Sarcoma of Lymph Follicles and its Association with Hodgkin's Disease, Lymphatic Leukaemia, and an Apparently Unique Disease of Lymph Nodes and Spleen Disease Thus Believed heretofore Undescribed. Reticulosis.—Symmers describes seven cases of a form of reticulosis to which he gives the name "giant follicular lymphadenopathy." One of these terminated in a condition for which he proposes the term "necrotic folliculitis"; this is said never to have been described before. Details are also given of seven further cases in which this form of reticulosis underwent malignant change, seven in which it was associated with Hodgkin's disease, and four with associated lymphatic leukaemia.

Oral Insulin.—The inactivation of insulin by proteolytic enzymes *in vitro* is a reaction which may be reversed in whole or in part. This finding suggested that under appropriate conditions the oral administration of insulin might be effective. Oral administration of insulin preparations in mice has consistently produced hypoglycaemic coma or convulsions within two hours of administration. The oral dose of undigested insulin hydrochloride was about ninety times the subcutaneous dose necessary to achieve the same effect. For digested insulin a dose of about forty-five times the subcutaneous dose was necessary. The authors suggest very tentatively that these observations indicate qualitative similarities between thyroglobulin and insulin with respect to the action of proteolytic enzymes.

New Syndrome of Infantilism.—Turner gives detailed accounts of seven cases of infantilism in female patients aged 15 to 23 years. All showed retardation in growth and sexual underdevelopment; webbing of the skin of the neck giving

apparent, though no real, shortening; and a markedly increased carrying angle at the elbow (cubitus valgus).

Premature Puberty.—Kunstadter describes two sexually retarded boys aged $11\frac{1}{2}$ and $10\frac{1}{2}$ years respectively. They were treated by the intramuscular administration of testosterone propionate. The first boy received twenty-one injections over sixteen weeks with a six-weeks rest period after the tenth injection, and the second boy received twenty-eight injections over six months with a two-and-a-half-months rest period after the eighteenth injection. In addition to the establishment of premature puberty in both cases, in the first case abnormal genital hypertrophy resulted.

*Ineffectiveness of β -aminopyridine in Black-tongue. F. M. Strong, R. J. Madden, and C. A. Elvehjem.—p. 2564. Y. Subbarow and W. J. Dunn.—p. 2565

β -aminopyridine in Black-tongue.—It is now agreed that this substance has no activity comparable with that of nicotinic acid in the treatment of black-tongue in dogs.

Sphenoid Artery. Y. H. Aasar.—p. 194.

Left Superior Vena Cava Draining Blood from Closed Coronary Sinus. A. F. Reed.—p. 195.

Thalamus of Chimpanzee.—The retrograde degeneration of cells in the thalamic nuclei has been studied, and the projection from the various nuclei to the cortex and subcortical areas mapped. Illustrations are given showing: (1) the ento-architectural divisions of the cortex, (2) the position and extent of the experimental lesions, and (3) the situation of the degenerated cells in the thalamic nuclei. The significance of the arrangement of the thalamic afferent (somato-sensory) and efferent connexions is discussed from the phylogenetic and functional viewpoints.

Piltdown and Swanscombe Skulls.—This resurvey of the anatomical features of the Piltdown Skull considered in the light of the discovery by Mr. A. Marston of the occipital and left parietal bones of a skull in the 100-foot terrace of the Thames Valley is of great general and scientific interest. Sir Arthur Keith presents a definitive reconstruction of the Piltdown Skull, founded on meticulously careful measurements and orientation of the bones and endocranial casts, which at once commends itself as being the best solution hitherto attempted of this difficult problem. The anatomical resemblance of the Swanscombe Skull to the Piltdown Skull is remarkable, and the author believes that they belong to a type which differs both from the Neanderthal type and from modern man, and which shows certain features which are definitely anthropoid.

Pyridine Compounds and Black-tongue.—From a qualitative study of the power of pyridine and eighteen of its derivatives to cure black-tongue in dogs when administered orally it appears probable that, besides nicotinic acid and its amide, only those compounds possess anti-black-tongue potency which are capable of oxidative or hydrolytic conversion in the body to nicotinic acid or amide. Thus, for example, the α and β isomers of nicotinic acid and methyl-nicotinic acid were inactive, whilst ethyl nicotinate and N -alkyl nicotinamides were active.

Renal Function as affected by Experimental Unilateral Kidney Lesions: I. Nephrosis due to Sodium Tartrate. T. F. Nicholson, R. W. I. Urquhart, and D. L. Selby.—p. 439.

Pulse and Lymph Flow.—A dye was injected interstitially at a distal point in the isolated rabbit's ear perfused with defibrinated blood and the rate of lymph flow deduced from studying the movement of the colour so produced. Perfusion

at constant pressure caused little flow, but when pulsation was imparted to the perfusing fluid the rate of flow increased. Pulsation in vessels therefore accelerates lymph flow, and the authors believe this to be due to the effect on tissues of rhythmic expansion of the larger vessels in them, and not to the forcing of fluid through capillary walls at each systole. Different rates of lymph flow in cardiac and renal oedema can be explained by a difference in the volume of the pulse in these two conditions.

Studies in Scarlet-fever Immunity. II. Plummer.—p. 234.

Action of Sulphanilamide.—In experiments on the effect of sulphanilamide on streptococci *in vitro* it was discovered that the presence of peptone interferes with the bactericidal action of this drug; when the cocci were separated from the peptone broth in which they had grown and re-suspended in serum an inoculum which would otherwise have grown was killed. Streptococci are able in the absence of sulphanilamide to utilize the constituents of serum for growth. The action of sulphanilamide in the body may therefore be an interference with the process whereby streptococci can utilize serum proteins for growth; the inactivation of the necessary enzyme would explain such an effect.

Studies of Morphine, Codeine, and their Derivatives: XIII. Clinical Study of Comparative Effects of Dihydrocodeine and Codeine. L. F. Davenport.—p. 236.

Alarm Reaction.—Selye has shown that substances not normally absorbed to any great extent from the alimentary tract (such as adrenaline and histamine) readily enter the blood stream if introduced into the stomach during an alarm reaction caused by muscular exercise or exposure to cold. He concludes that the increased absorption of toxic substances, such as are usually present in the alimentary tract, probably plays an important part in the causation of the general damage resulting from various non-specific noxious agents.

Thyrotoxic Heart.—The response of the normal and of the thyrotoxic heart to the administration of mechoyl (acetyl- β -methylcholine chloride) and of adrenaline is a physiological one, in which an attempt is made to adjust the disturbed autonomic balance in the cardiovascular system. The response of the thyrotoxic heart to these substances is greatly exaggerated and is considered to be due in part to augmentation of the effect of existing acetylcholine and sympathin in the thyrotoxic heart. Experiments described also suggest the existence in the thyrotoxic heart of increased sensitivity to these two substances.

*Nissl Granules in "Fatigued" Nerve Cells. E. M. Scarborough. —p. 184.

Ephedrine.—Low concentrations of ephedrine sensitize the rabbit's ear, the cat's nictitating membrane, and the frog's heart not only to adrenaline but also to stimulation of adrenergic nerves. These actions of ephedrine are attributed to the inhibition of amine oxidase, which oxidizes adrenaline. This inhibition is compared with the inhibition of cholinesterase by eserine.

Iron.—Three men and three women were placed upon diets containing 5.9 to 8.6 mg. of iron a day and shown to be in balance. Then the oral intakes were raised to 12 to 16 mg. of iron a day and the subjects were again shown to be in balance—that is, all the supplementary iron was excreted. Later 7 mg. of iron were injected intravenously every day, the intake by mouth being from 7.6 to 11.7 mg. a day. None of the injected iron was excreted into the gastro-intestinal tract; the intestine has no power of regulating by excretion the amount of iron in the body.

Nissl Granules.—Prolonged stimulation of the autonomic ganglia in cats produces no change in the appearance of the Nissl granules of the nerve cells.

***Radiosensitiveness of Ewing's Tumours.**—The immediate response of the tumours to radiotherapy is good, but the patient as a rule dies after a year or so from local recurrences or distant metastases. Only three out of eighteen cases reviewed survived for an appreciable length of time. One of these cases was treated with radiotherapy alone, one with surgery alone, and in the third case surgery was combined with radiotherapy. This last procedure the author advocates as the method of choice.

Radium Therapy of Haemangioma.—The author favours the interstitial application of radium needles and reports favourable results in 230 cases so treated.

Neutrons.—The movement of fast neutrons is slowed down by collision with hydrogen, which is present in practically all the tissues of the body. The slowed-down neutrons adhere to a number of atoms such as those of sodium and potassium; this produces in the body a hard x-radiation. The newly formed atoms are radio-active and emit over a variable length of time (seconds to hours) β rays, which are absorbed in the body.

Trypaflavine in Psittacosis.—Trypaflavine prolongs the life of mice experimentally infected with the virus of psittacosis, and if the dose of the latter be not too great may even save the life of the animal. The results of such experiments vary with the route of administration both of the virus and of the trypaflavine, which is least effective when given intravenously (presumably owing to rapid elimination). Its action may be either direct or indirect: if the former, its capacity for penetrating cells is likely to be an important factor.

HORMONE TREATMENT

in imperfect descent of the testis

"The disadvantage of waiting for spontaneous descent in any except the retractile type is that if an anatomical abnormality be present, the diagnosis of which may deceive even the elect, spontaneous descent can never occur. Waiting until after puberty in the hope of spontaneous descent is in such a case an unnecessary and unjustifiable delay. Analysis of the results in the present series shows that if in cases of doubt a retained testis does not respond after six months of hormone treatment, it is highly probable that there is an anatomical abnormality."

ALUZYME PRODUCTS,
PANK ROYAL ROAD, LONDON, N.W.10.

TOTAL VITAMIN B ACTION

Disappointing results with Vitamin B₁, given alone, confirm the claim that the entire B Complex should be administered in all deficiency conditions. The B Vitamins form a synergy; each factor contributes to the corrective action. Aluzyme supplies all these factors in a fully active state and is demonstrably the best available source of the complete B Complex. B₁ Potency: 1140 International Units per oz. Active response to nicotinic acid, glutathione and flavin tests. Indications: Avitaminosis B and resulting conditions, anaemias, colitis, many nervous and skin affections.

Apply: RESIDENT MEDICAL OFFICER.

WYE HOUSE, BUXTON, AND CLINIC.

for the PREVENTION and TREATMENT of NERVOUS and MENTAL DISORDERS in both sexes. Large country house beautifully situated in its own grounds. Croquet lawns, hard tennis court, billiards, wireless installation throughout. Every facility for specialised modern treatment, including psychotherapy, occupational therapy, ultra-violet light, diathermy. Private rooms with special nurses, if required. Voluntary, Temporary and Certified patients received.—For terms, apply to the Medical Superintendent, HELEN S. E. NUTTEY, M.D. Nat. Tel. 130.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D., M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

CRICHTON ROYAL, DUMFRIES

for
NERVOUS AND MENTAL DISORDERS

Cases of alcoholism and drug addiction are admitted.

This Hospital has every facility for complete investigation and treatment of the above conditions.

The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy. There is a fully equipped Gymnasium and indoor Swimming Bath under qualified instructors. Facilities are provided for all indoor and outdoor recreation, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens, and a Cinema.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country, and include an extensive farm (T.T. herd), gardens and orchards.

Private rooms, suites or villas are available, and special nurses can be provided. As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week; Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Supt: P. K. MCCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law. Tel.: Dumfries 1119.

The Practice of the Hospital is limited to Medical Practitioners. Particulars from I. BROWNING ALEXANDER, M.D., Dean.

BIRKENHEAD EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for the position of Assistant School Medical Officer at a salary of £500 per annum, rising by annual increments of £25 to a maximum of £700. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and will carry with it the designation of "Assistant School Medical Officer and Assistant Medical Officer of Health."

In fixing the commencing salary within the scale regard will be paid to previous recognized service. The duties will mainly consist of the inspection and treatment of children attending schools in the Borough.

Applicants must be duly qualified Medical Practitioners with experience and must hold the Diploma of Public Health.

The person appointed will be required to reside within the Borough.

Canvassing, either directly or indirectly, will be regarded as a disqualification.

Particulars of the appointment and form of application may be obtained from Dr. D. Morley Mathieson, Medical Officer, 9, Hamilton Square, Birkenhead, and applications must be delivered not later than January 14th, 1939, to:

G. B. DEMPSEY,

Education Officer, Director of Education.
Hamilton Square, Birkenhead.

CHESHIRE EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER (Woman).

Applications are invited from qualified single women for a whole-time post as Assistant School Medical Officer, to reside at Altrincham.

Candidates must have had at least three years' practical experience in their profession and be not more than 45 years of age.

Commencing salary £500, rising by £25 annually to £700 (less 5 per cent. for superannuation). Travelling expenses on County scale.

Forms of application, containing full particulars of appointment, may be obtained from the undersigned and must be received, duly completed, not later than January 9th, 1939.

JAN MACKAY, M.B., Ch.B.,

School Medical Officer.

24 Nicholas Street, Chester.

UNIVERSITY OF DURHAM.

King's College, Newcastle-upon-Tyne.

ASSISTANT BACTERIOLOGIST IN PUBLIC HEALTH LABORATORY.

Applications are invited from qualified medical men or women for the above post. Postgraduate experience in the routine methods of a bacteriological laboratory is desirable. The appointment is a temporary one in the first place, but a permanent appointment will shortly be made. The person will be required to take up duty at the earliest possible date. Salary at the rate of £400 per annum. Applications should be lodged as soon as possible with the undersigned.

W. G. B. OLIVER,

Registrar.

GUY'S HOSPITAL DENTAL SCHOOL.

Applications are invited for the WHOLE-TIME POST OF DENTAL RESEARCH FELLOW, the appointment to begin as soon after January 1st, 1939, as possible. Preference will be given to a biochemist who is prepared to undertake work on dental diseases. The appointment will be for two years in the first instance with the possibility of reappointment. The stipend will be at the rate of £400 per annum.

Applications, accompanied by the names of three persons to whom reference may be made, should be submitted not later than December 31st, 1938, to the Dean, Guy's Hospital Medical School, S.E.1, from whom further particulars regarding the appointment may be obtained.

CITY OF BIRMINGHAM.

Dudley Road Hospital. (926 Beds.)

Applications are invited from fully qualified Medical Practitioners for whole-time appointment as JUNIOR MEDICAL OFFICER (male) at the Dudley Road Hospital, Birmingham. The appointment will be for a period of six months, but may be extended for a further period of not exceeding six months. Salary at the rate of £200 per annum, and full residential emoluments.

Further particulars may be obtained from the Medical Superintendent at Dudley Road Hospital, to whom applications, stating age, experience, and qualifications, with copies of recent testimonials, should be forwarded not later than Thursday, December 29th, 1938.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry at the end of March, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list. Marriage Allowance is paid under the same conditions as for other Naval Officers.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1939.

SURREY COUNTY COUNCIL PUBLIC HEALTH DEPARTMENT.

EPSOM COUNTY HOSPITAL. (330 Beds)

RESIDENT ASSISTANT MEDICAL OFFICER (Male)

Applications are invited for the appointment, which will be vacant on February 1st, 1939, of Resident Assistant Medical Officer at the Epsom County Hospital.

Applicants must have held a previous resident hospital appointment and should preferably have had experience in maternity work and minor surgery.

The appointment is for a period of six months, renewable for a further period of six months, and the salary is at the rate of £250 per annum, together with full residential emoluments valued at £125 per annum.

Applications, stating age, qualifications, and experience, and enclosing copies of not more than three recent testimonials, should be addressed to the Medical Superintendent, Epsom County Hospital, Dorking Road, Epsom, so as to be received not later than December 31st, 1938.

DUDLEY AUKLAND
County Hall, Kingston-upon-Thames.
December 16th, 1938. Clerk of the Council.

CITY OF LEICESTER.

RESIDENT MEDICAL OFFICER.

Resident Medical Officer (male) required for the CITY ISOLATION HOSPITAL AND SANATORIUM, Groaty Road.

Appointment for a period of six months, renewable if service is satisfactory for a further period of six months.

Salary at the rate of £300 per annum, with the usual residential emoluments. The officer appointed must be required to assist with Infant Welfare work.

Applications, on forms to be supplied, to be sent to the undersigned not later than January 11th, 1939.

Health Offices, E. K. MACDONALD,
Grey Friars, Medical Officer of Health
Leicester, December, 1938.

BOROUGH OF ROMFORD.

WOMAN ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

Applications are invited from duly qualified and registered medical practitioners for the post of whole-time Woman Assistant Maternity and Child Welfare Medical Officer experienced in Ante-Natal work, Midwifery and Children's Diseases. Preference will be given to applicants who hold a Diploma in Public Health or State Hygiene. The selected candidate will be required to hold consultations at the Ante-Natal and Maternity and Child Welfare Centres of the Council, and to perform such other duties as may be required of her. She will be a member of the staff of the Medical Officer of Health, and will work under his control and direction.

The salary will be £590 per annum, rising by annual increments of £25 to a maximum of £700 per annum.

The person appointed will be required to devote the whole of her time to the duties of her office and will not be allowed to engage in private practice.

The post is subject to superannuation deductions, and the selected candidate will be required to pass satisfactorily a medical examination.

Applications, stating age, qualifications, and previous experience, accompanied by copies of not more than three recent testimonials, should be endorsed "Assistant Medical Officer," and delivered to me not later than Saturday, January 7th, 1939. There are no forms of application. Candidates in any form will disqualify.

Town Hall,
Romford.
December 14th, 1938.

J. TWINN,
Town Clerk.

CLAYTON HOSPITAL WAKEFIELD

CASUALTY OFFICER in charge of Fracture Clinic. Previous practice and plaster technique essential. Required February 1st, 1939, for minimum period of one year. Candidates should be of British nationality, male, and single. Salary £250 p.a., with board, residence, etc.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be sent to the undersigned by December 31st, 1938.

T. F. W. MACKEOWN,
Superintendent and Secretary.

COUNTY BOROUGH OF BLACKBURN.

ASSISTANT SCHOOL MEDICAL OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH (Male)

Applications are invited from registered medical practitioners for the post of Assistant School Medical Officer and Assistant Medical Officer of Health (male) to act under the supervision of the Medical Officer of Health, who is also the School Medical Officer.

The person appointed must devote the whole of his time to the service of the Corporation.

The duties of the office are general, although they will consist largely of work in the School Medical Department. Preference will be given to candidates holding a Diploma in Public Health who have held resident appointments in general and infectious diseases hospitals.

The salary will be at the rate of £600 per annum, increasing by annual increments of £25 to a maximum of £700 per annum.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Forms of application and further particulars of the duties and conditions of the appointment may be obtained from the Medical Officer of Health, Victoria Street, Blackburn.

Completed forms, together with copies of three recent testimonials, must reach me by Friday, January 6th, 1939, and should be endorsed on the envelope "Assistant School Medical Officer."

Candidates, either directly or indirectly, will be disqualified.

Town Hall, CHAS. S. ROBINSON,
Blackburn. Town Clerk.

THE BUCHANAN HOSPITAL, St. Leonards-on-Sea. (103 Beds)

HOUSE SURGEON (female) required to commence duties early in January. Salary £125 per annum, experience.

Candidates must be duly registered Medical Practitioners, and applications, which should include three copies of recent testimonials, should be sent to the undersigned immediately.

FRANK HART,
Secretary.

CITY OF LEEDS. PUBLIC HEALTH DEPARTMENT. St. James's Hospital. (1,330 Beds.) RESIDENT MEDICAL OFFICER (Male).

Applications are invited for the above appointment, the duties of which are entirely medical. Candidates must be single, and should have had considerable experience in general medicine and possess one of the higher qualifications. The position offers excellent opportunity for extensive experience in medicine. The person appointed will be required to work under the direction of the Medical Superintendent and in association with the Visiting Physicians. He will also have the supervision of the immediate clinical work of four House Physicians.

Under the present scale of salaries of the Corporation the commencing salary for the post is £350 per annum, and the maximum £450 per annum, with annual increments of £25, subject to satisfactory service. The first increment will take effect on April 1st, following the completion of twelve months' service. Board, residence, and laundry are provided, these emoluments being valued for superannuation purposes at £120 per annum.

The person appointed will be required to pass a medical examination and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922.

The appointment will be terminable by one month's notice.

Applications, on a form to be obtained from the undersigned, together with copies of three recent testimonials, and endorsed "Resident Medical Officer," must be received at the Public Health Department, 12, Market Buildings, Vicar Lane, Leeds 1, not later than 10 a.m. on Monday, January 9th, 1939.

Canvassing in any form, either directly or indirectly, will be a disqualification.

J. JOHNSTONE JERVIS,
Medical Officer of Health.

ESSEX COUNTY COUNCIL. JUNIOR RESIDENT MEDICAL OFFICER.

The County Council of the Administrative County of Essex invite applications for the appointment of a Junior Resident Medical Officer at the Oldchurch County Hospital, Romford.

The appointment is for a period of one year, and the salary will be at the rate of £250 per annum, together with the usual indoor emoluments valued at £160 per annum. The successful candidate will be required to pass a medical examination, and will be subject to the Council's sick pay rules and regulations, a copy of which will be forwarded on application.

Applications on the prescribed form obtainable from the undersigned should be addressed to me, and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Saturday, December 31st, 1938.

County Hall, E. S. HOLCROFT,
Chelmsford. Clerk of the County Council,
December 13th, 1938.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing to undermentioned positions. Candidates must have held resident appointment in a general hospital for at least six months. Married quarters not available.

ASSISTANT MEDICAL OFFICERS (Class 1).—Salary £350-£25-£425, with board, lodging and washing.

(a) ST. GILES' HOSPITAL, St. Giles' Road, Camberwell, S.E.5.—Surgical experience desirable.

(b) ST. JAMES' HOSPITAL, Ouseley Road, Balmam, S.W.12.—(Two positions.) (1) Surgical duties. (2) Obstetric and gynaecological duties.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division, 2, County Hall, Westminster Bridge, S.E.1, returnable by January 2nd. Canvassing disqualifies.

SOMERSET COUNTY COUNCIL. APPOINTMENT OF ASSISTANT (TEMPORARY) MEDICAL OFFICER

Applications are invited for the above appointment from registered medical practitioners (men or women). The duties will be concerned mainly with school medical inspection, and the probable duration of the appointment will be six months.

Salary £500 per annum. Travelling and subsistence allowances according to County scale.

Applications, stating age, qualifications, and experience, with copies of recent testimonials, should be sent immediately to the undersigned.

J. F. DAVIDSON,

County Medical Officer of Health
Health Department,
County Hall, Taunton

COUNTY OF BRECON. APPOINTMENT OF DISTRICT MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of District Medical Officer of Health for the combined areas of the Borough of Brecon, the Urban Districts of Builth Wells, Hay, and Llanvrttyd, and the Rural Districts of Brecknock, Builth, and Hay (360,216 acres, population about 25,000), from April 1st, 1939.

Applicants must be registered in the Medical Register as the holder of a Diploma in Sanitary Science, Public Health, or State Medicine, and must not be over 45 years of age at the date of application.

The person appointed will be required to perform all the duties imposed on a Medical Officer of Health by Statute and by any Orders, Regulations, or directions from time to time made or given by the Minister of Health and by any by-laws or instructions of the Local Authorities concerned in the appointment applicable to the office, and to devote the whole of his time to the duties of his office.

In addition he will be required to undertake the organisation of the Medical services of the above districts forming part of the Air Raid Precautions Scheme for the County under the general directions of the County Medical Officer of Health and the County Co-ordinating Officer, and he may be required to undertake a certain amount of work in connexion with the medical services provided by the County Council.

Salary £800 per annum, together with an allowance of £100 per annum for travelling, subsistence, provision of office accommodation, and clerical assistance.

The appointment is subject to the approval of the Minister of Health and is pensionable under the provisions of the Local Government Superannuation Act, 1937.

Applications, giving age, medical qualifications, and previous experience (if any), together with copies of three recent testimonials, must be received by me not later than January 14th, 1939.

ALBERT JOLLY,

County Hall, Brecon. Clerk to the Breconshire County Council,
December 16th, 1938.

COUNTY BOROUGH OF DERBY. ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the post of Assistant Medical Officer in the Public Health and School Medical Department. Salary £500 per annum, rising by annual increments of £25 to £700 per annum.

Applicants must be duly qualified registered Medical Practitioners, and should possess the Diploma of Public Health.

The duties of the post are the medical inspection of school children, the supervision of treatment of minor ailments, the carrying out of work under the maternity and child welfare scheme, and such other duties as may be required by the Council.

The officer appointed will be required to devote his whole time to the duties of the post, to act under the supervision and control of the Medical Officer of Health, and to reside within the Borough.

The successful candidate will be required to contribute to the Council's Superannuation Fund, and for this purpose must pass the necessary medical examination. Age of applicant must not exceed 40 years.

The appointment will be held during the pleasure of the Council, and is terminable by two months' notice on either side.

Applications, stating age, qualifications, and previous experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than Wednesday, December 28th, 1938. Application forms are not provided. Envelopes must be endorsed "Assistant Medical Officer."

Canvassing, directly or indirectly, will be a disqualification.

F. C. SMITHARD,
Secretary to the Education Committee.
Education Offices,
Becket Street, Derby.

COUNTY BOROUGH OF BRIGHTON. APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Council invite applications for the appointment of Medical Officer of Health at a salary of £1,250 per annum, rising by annual increments of £50 to a maximum of £1,750.

Forms of application, together with the qualifications, duties and conditions required or attached to the position may be obtained from me.

Applications (with copies of three recent testimonials) and endorsed "Medical Officer" must be delivered at my Office before 10 o'clock in the forenoon of Tuesday, January 10th, 1939.

Canvassing, either directly or indirectly, will disqualify.

Town Hall, Brighton.
J. G. DEW,
December 19th, 1938. Town Clerk.

MIDDLESEX COUNTY COUNCIL.

(1) DISTRICT MEDICAL OFFICER.
HORNSEY MEDICAL RELIEF DISTRICT.
Qualified Medical Practitioner* required for above appointment. Salary £300 p.a., plus cost of expensive drugs, fees for attendance at confinements and for services of another medical practitioner to administer short anaesthetics for minor operations (e.g. septic fingers, abscesses).

The officer appointed will be required to carry out his duties in accordance with the Public Assistance Order, 1930, of the Minister of Health, to reside in the district unless the Council otherwise determines, and to name to the Council some duly qualified medical practitioner who will, in the case of his absence or other hindrance to his personal attendance, act in his place.

(2) PUBLIC VACCINATOR.
HORNSEY VACCINATION DISTRICT.
Qualified Medical Practitioner* required for above appointment. Will be required to produce to the Council a certificate of proficiency in vaccination, except in a case in which such certificate was required as a condition of obtaining any diploma, licence or degree which he possesses. He will be required also to enter into a contract with the Council in accordance with the Vaccination Order, 1930, of the Minister of Health. The contract will provide for the payment of the scale of fees laid down by the County Council.

(3) ASSISTANT DENTAL OFFICER.
Fully qualified and registered Dental Surgeon required for pensionable staff, subject to medical examination. Duties include dental inspection and treatment of school children and of women and young children under Maternity and Child Welfare Scheme. Whole-time duties under supervision of County Medical Officer and Senior Dental Surgeon. Private practice not allowed. Salary £500 p.a., £25-£700, with out-of-pocket travelling expenses whilst on duty.

*No superannuation rights under Council's Scheme in these cases.
Applications, stating date of birth, qualifications and experience, with copies of not more than three recent testimonials, must reach the undersigned by January 7th, 1939 (Dental Officer, January 10th). Envelopes must be endorsed either "District Medical Officer—Z," "Public Vaccinator—Z," or "Dental Officer—Z." No application forms. Canvassing, direct or indirect, disqualifies.

C. W. RADCLIFFE,
Guildhall, Westminster, S.W.1.
Clerk of the County Council.

COUNTY BOROUGH OF MIDDLESBROUGH.

ST. LUKE'S MENTAL HOSPITAL.
Grove Hill, Middlesbrough.

The Committee of the County Borough of Middlesbrough invite applications for the appointment of an OFFICER and INTENDENT (male) for the above-mentioned Hospital.

Candidates must be fully qualified and duly registered, and preference will be given to one who has held a resident appointment in a General Hospital.

The age of applicants, unless with previous Mental Hospital service, should not exceed 35 years.

Salary £500 per annum (no emoluments), rising by four annual increments of £25 to a maximum of £600, plus an extra payment of £50 per annum to holders of, or who may later obtain, the D.P.M. Unfurnished house on the estate provided, for which a sum of £50 per annum will be deducted from the salary to cover rent, rates and water.

The appointment is whole time and subject to the provisions of the Asylums Officers' Superannuation Act, 1909. The appointment will be terminable by two months' notice on either side. The successful candidate will be required to undergo a medical examination.

Canvassing will disqualify.

Applications, accompanied by copies of three recent testimonials, should be sent to the undersigned not later than January 4th, 1939, endorsed "Assistant Medical Officer and Deputy Medical Superintendent."

PRESTON KITCHEN,
Town Clerk and Clerk to the
Town Clerk's Office, Committee of Visitors
Middlesbrough
December 7th, 1938

THE BABIES' HOSPITAL. Newcastle-on-Tyne.

NON-RESIDENT MEDICAL OFFICER
required February 1st.

The duties are those of a Resident Physician, and the post offers opportunities for study and research work. The appointment is for six months, which may be extended to twelve months. Salary £160 per annum.

Applications, with two testimonials and particulars of previous appointments held, must be lodged by January 4th with the Secretary, Babies' Hospital, West Parade, Newcastle-on-Tyne.

APPOINTMENTS—Important Notice

Medical practitioners are requested not to apply for any appointment referred to in the following table without having first communicated with the Secretary to the British Medical Association, B.M.A. House, Tavistock Square, W.C.1 (in the case of Scottish appointments, with the Scottish Secretary, 7, Drumsheugh Gardens, Edinburgh).

1000 Patients
 need not go
 without Nummol
 if the doctor considers
 them deserved have
 it

Although NUMOL is an expensively produced article, it is available for everybody and not only for well-to-do people.

Even when it is bought in the ordinary way, it is cheap and economical to use having regard to its small concentrated doses and to its therapeutic properties, but there are schemes in operation to provide for it being available for even the poorest patient.

It can be obtained for Hospitals at special prices packed in Hospital Containers, and it is also available through all Welfare Centres.

In addition to all these schemes, free supplies can be obtained by Doctors for special cases, and half price supplies are available for patients who are not exactly destitute, but cannot afford to pay the ordinary price. Doctors are invited to write for full particulars.

LONDON

BRITISH MEDICAL ASSOCIATION

TAVISTOCK SQUARE

BIOLOGICAL investigation was commenced by Parke, Davis & Co. forty years ago. In 1898 the firm produced the first 2000-unit per c.c. diphtheria antitoxin ever obtained. Biological work developed so extensively that, in 1908, a biological farm was established for the production of serums, antitoxins, etc.

THE PARKE-DAVIS BIOLOGICAL FARM

THIS experimental and biological farm, maintained by Parke, Davis & Co., near Rochester, Michigan, about 30 miles north of Detroit, covers one square mile, and is devoted mainly to the production of serums, antitoxins, and other biological products. More than 40 buildings, arranged in units, house several hundred horses and a large herd of cattle. Several thousand small animals, such as goats, pigeons, rabbits and guinea-pigs, are included among the livestock of this large farm. The large area has made it possible to place the quarantine building fully a mile from the other buildings which are constructed and arranged with special regard to the purposes for which they are used. Each type of work is segregated in a separate unit housed by itself and utilizing its own equipment. Most of the stables have a capacity of 50 horses each, and all are well lighted and ventilated. Special operating rooms are used for injecting and bleeding the horses used for serum production. Other auxiliary buildings which have been designed for individual purposes include the central heating and power plant, the post-mortem room and the dipping building, where disinfecting baths are given to all horses and cattle.

'HANGERS' of ROEHAMPTON have Revolutionized Limb-Fitting Practice

A TYPICAL CASE. HISTORY.—Female, aged 16. Double congenital deformity with double congenital dislocation of the hip. Feet in fibrous union with the condyles of the femur in a position of double inversion, pointing backwards with the soles upwards.

PROSTHESES.—Light-metal artificial limbs with blocked leather ischial bearing thigh corsets; supporting steels articulated at the knees with specially designed locking joints; light-metal one

piece seamless shins; articulated ankles and toe joints. All weight is taken on the tuberosity of the ischium, the rudimentary feet resting on platform of knee.

PROGRESS.—Walks well without a stick; uses a stick outdoors only, as a safeguard against being jostled. Travels daily to and from her work, earning her living as a typist; wears her appliances all day in complete comfort. Normal appearance, sitting or standing.

POST FREE TO THE MEDICAL PROFESSION:

"*SOLVITUR AMBULANDO*." 72 Pages, 37 Coloured Plates. This book deals exhaustively with the whole problem of providing prostheses for every type of amputation.

THE PRACTITIONER

FOR 1939

Edited by

SIR HUMPHRY ROBERTSON, Bt, GCVO, KCB, M.D., FRCP, and ALAN MONCRIEFF, M.D., FRCP.

For 1939 *The Practitioner* has arranged an important programme of practical articles for the general practitioner. The series on Diet in Health and Disease will be continued in the early part of 1939, when various aspects of diet in infancy and childhood will be dealt with by experts. In addition, a series of articles has been planned dealing with the work which a general practitioner might be called upon to perform in a national emergency.

The following symposia will be published during the next three months:

JANUARY

DISEASES OF THE SKIN

This number includes the following articles:—Importance of Diet and General Treatment—Psychological Aspects—Significance and Treatment of Itching—Pyogenic Injections—Treatment of New Growths—Modern Views on the Treatment of Eczema—Alopecia. This number will also include articles on Fear—First Aid in Air Raids—General Principles of Diet in Childhood. 136 pages of text. Price 4s.

FEBRUARY

MIDWIFERY IN GENERAL PRACTICE

This number will contain the following articles:—Midwifery and the General Practitioner—The Management of the Puerperium—Ante-natal Care—Delayed Labour—Diagnosis and Treatment of Disproportion—Equipment and Instruments—Breast Feeding. Also the Treatment of War Injuries in Casualty Clearing Stations, and articles of General medical interest. Price 4s.

MARCH

AFFECTIONS OF THE HANDS AND FEET

The articles in this symposium will include:—Common Vascular Disorders—Congenital Abnormalities—Surgical Conditions—Sprains and Fractures—Skin Disorders—The Management of Flat Foot. Other articles will include Artificial Feeding—Treatment of War Injuries in Base Hospitals. Price 4s.

APRIL

A Special Number will be published on a subject of importance to every general practitioner. Price 7s. 6d.

The annual subscription, which includes two Special Numbers, is £2 2s. post free to any part of the World.

SUBSCRIPTION FORM

To the Publishing Department,
The Practitioner,
5, Bentinck Street, London, W.1.

I enclose remittance value £2 2s. Please send to me *The Practitioner* post free for one year beginning with the number; subscription to include two Special Numbers without extra cost.

Medical Opinion endorses the

"SIDHIL"

**TILTABLE BED
and BED DONKEY**

This tilting bedstead serves many alternative positions and opens up countless new opportunities in the treatment of surgical and medical cases. The feet-down (Fowler) position is needful after abdominal operations, in Pneumonia and Heart cases; the head-down position for shock after Spinal Anæsthesia; and in paralysis of the Diaphragm, Diphtheria cases, etc., life may be saved by rocking the bed.

The much-improved Bed Donkey prevents the patient slipping, minimises bed-sores, and adds greatly to the comfort and effectiveness of the bed.

"SIDHIL" Tilting Bedstead No. 549 (Reg. Design), with Bed Donkey No. 66 (Reg. Design). Note the ease with which an effective and desirable tilt can be attained and clamped.

IF IT'S "SIDHIL" IT'S SOUND

We shall be glad to send full particulars of the "SIDHIL" Range of Hospital Equipment to all interested.

TO THE MEDICAL PROFESSION STRATSTONE MAKE THIS SPECIAL OFFER

A FEW DAIMLER '15's less than *one* year old AT A BARGAIN PRICE

** Generous allowance made for your present car.*

As a physician you realise the importance of reliability, comfort and dignity in the car you drive. You have probably heard the Daimler referred to as 'The Doctor's Car'—a title it has earned because it so perfectly fulfils the requirements of the practitioner. The Daimler has, indeed, become traditionally associated with the medical profession. Since it is conceivable that eventually you will own a Daimler, you will be interested to learn that we have a few small mileage 1938 Daimler '15' Saloons for quick disposal to the medical profession at a greatly reduced price.

These cars, still under our guarantee, have been most carefully maintained, are similar in design to the latest 1939 models, and have the renowned Daimler Fluid Flywheel for quick change,

acceleration, speed and silence. Original price £475. Now offered at £350.

An exceptional opportunity is here presented for you to buy a Daimler at a reasonable cost with a generous allowance for your present car in part exchange. You will own one of these Daimlers with pride and drive it with pleasure for many years to come.

We have also in stock a few 1937 small mileage Daimler Saloons for which we are prepared to accept £250. These cars, too, are in excellent condition. Write for photos and specifications, stating the model in which you are interested, or better still, arrange for a demonstration. Distance no objection. We have satisfied clients all over the United Kingdom.

If preferred, the sale can be arranged through your usual local dealer.

EARLY APPLICATION IS ADVISED

STRATSTONE

27 PALL MALL - 40 BERKELEY ST.

Modern Iron Therapy

Iron Jelloids are an elegant and reliable means of administering the protoecarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidised indefinitely, and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

The Iron Jelloid Company, Ltd., King George's Avenue, Watford, Herts.

Anti-Cold—Anti-Influenza

INOCULATION BY THE ORIGINAL VACCINE
IN TABLET FORM

BUCCALINE

Made in Switzerland by the Serum and Vaccine Institute under the supervision of Dr. G. Sobernheim, Professor of the University of Berne.

Under normal conditions Buccaline Tablets will give protection against Colds and Influenza for a period of four to six months.

The Director of the Barmelweid Sanatorium in Switzerland, Dr. Werner Jost, writes in an article appearing in the *Swiss Medical Journal* :—

"I have, in the last three years, tested Buccaline on nearly 900 people, sick and healthy. The effects appear to me so clear that the vaccine should be as generally used as possible."

Set of Three-Immunising Doses:

Adults, 5/- per tube (post free).

Children (over 4 years), 3/6 per tube (post free).

Literature on request.

KOROMEX METHOD

The Koromex Occlusive Diaphragm is made in a range of sizes to fit each individual patient; pure latex rubber pessaries. Light and comfortable; practically unfelt. Two-year durability guaranteed. Practitioners and birth control clinics, for more certain protection, prefer to use the perfect fitting Koromex Diaphragm with

KOROMEX VAGINAL JELLY

Stainless and prolonged effective spermicide. The carefully gauged viscosity of Koromex Jelly affords the all-important mechanical block. No toxicity or irritation . . . makes the diaphragm easier to insert.

Advise the Koromex Method. Your patient will be grateful.

A sample of Koromex Jelly will be sent on application to medical practitioners; also a booklet, the 'Physician's Guide, on the technique of fitting the Occlusive Koromex Diaphragm. No charge. Write to

The Highest Record of PROVEN SUCCESS in Contraceptives

- Evidence of the high degree of efficacy of the Koromex Method is based upon the experience of 234 clinics—140 hospitals—over 50,000 physicians.

THE KOROMEX METHOD
KOROMEX DIAPHRAGM + KOROMEX JELLY

- The Koromex Diaphragm appears on the National Birth Control Association's approved list with seven Prentif products, including Condoms, Sheaths, Jellies and Suppositories. Illustrated descriptive Price List on request.

OVALTINE

IN PREGNANCY

THE physiological drain of calcium, phosphorus, vitamins and other important food elements calls for replacement during pregnancy. Composed of milk, eggs and malt, 'Ovaltine' supplies these essentials in a delightful form which does not overtax the unstable maternal digestion. A cup of 'Ovaltine' on arising, during the early months, is often effective in controlling sickness and has a food value greater than three eggs.

IN LACTATION

To maintain lactation to the eighth month is an ideal not often realized under modern conditions of life. Ample evidence is available to show that 'Ovaltine' has a definite action in increasing the flow and enriching the quality of the milk. It has, moreover, a beneficial effect on the health of mother and child. The flavour is so agreeable that it can be taken for prolonged periods without any distaste arising.

CONTRAMINE

In the Treatment of Chronic Rheumatism

It has been demonstrated repeatedly by clinical trials and in the ordinary routine of general practice that Contramine is an exceedingly useful product for the treatment of chronic rheumatism, whether it is of gonococcal origin or not. Chronic cases which have withstood other forms of treatment have shown marked improvement after a series of injections of Contramine.

A physician reporting upon his experience in the use of Contramine in a case of rheumatism which he suspected was subsequent to gonococcal infection stated that he had '... marvellous results, the rheumatism clearing up completely'.

Contramine is supplied in ampoules of 1 c.c. and 2 c.c. containing the drug in sterile solution for intramuscular injection.

"THEY NEVER PRODUCE FEVER OR THROMBOSIS"

These words were used by one of England's leading Surgeons in describing Baxter's Intravenous Solutions in the "Vacoliter" container.

For years unfavourable reactions after Intravenous Therapy were looked upon as a natural accompaniment to surgery. Not any more. Safe Solutions have changed all that. To-day thousands of Surgeons know that Baxter's Intravenous Solutions in the "Vacoliter" container are unquestionably safe—and that they never produce unfavourable reactions.

Baxter's Intravenous Solutions are a FINE BRITISH PRODUCT obtainable in Great Britain from:—

JOHN BELL & CROYDEN

Sole distributors for

BAXTER LABORATORIES LIMITED,
24, CONWAY ROAD, LONDON, N.15.

A good source of vitamins A, B and C.

If any of your patients require a change of fruit juice in their diet, you can recommend Dole Pineapple Juice with confidence; for not only is it a good source of Vitamins A, B and C and natural fruit sugars, but it is also a delicious and tempting drink.

A TYPICAL ANALYSIS WILL SHOW YOU WHAT DOLE PINEAPPLE JUICE IS COMPOSED OF:—

| | |
|---|------|
| Moisture | 85.3 |
| Acid | 0.4 |
| Fat (other extract) | 0.3 |
| Protein (N x 6.25) | 0.3 |
| Crude fibre | 0.02 |
| Titrate acidity as citric acid | 0.9 |
| Reducing sugars as invert sugar | 12.1 |
| Carbohydrates other than sugars (by difference) | 0.38 |

Dole Pineapple Juice is the pure, unsweetened juice of selected Hawaiian pineapples, packed by the exclusive Dole Fun-Seal Vacuum Packing Process.

Dole Pineapple Juice in the special tins reaches you field-fresh from sunny Hawaii.

Write us on your letterhead and we will send a sample tin.

RICHMOND, VIRGINIA, U.S.A.

"For a Tired Stomach"

Advise a laxative

that is safe, gentle, and palatable.

Lixen is an extract of senna prepared by a special cold process to allay the griping action. The absence of an after-constipating effect gives it a special value in habitual constipation, and its gentle, though efficient, action, together with its pleasant flavour, makes it particularly acceptable to women, children, elderly and delicate persons, and convalescents, for whom the finding of a satisfactory aperient is often difficult.

LIXEN Elixir in bottles of 2 oz. 1/-, 4 oz. 1/9, 8 oz. 3/-, 16 oz. 5/6. In bottles of 40 and 80 oz. for dispensing.

LIXEN Laxative Lozenges in tins of 12, 7½d., 24, 1/-, and bottles of 100, 3/6. In bottles of 500 for dispensing.

Descriptive literature and clinical sample will be sent on request

Ergoapiol (Smith)

A Menstrual Regulator...

When the periods are irregular, due to constitutional causes, ERGOAPIOL (Smith) is a reliable prescription. Containing apiol (M.H.S. special) together with ergot, aloin and oil of savin of the highest quality, this preparation effectively stimulates uterine tone and controls menstrual and postpartum bleeding.

In cases of Amenorrhoea, Dysmenorrhoea, Menorrhagia and Metrorrhagia, Ergoapiol serves

as a good uterine tonic and hemostatic. Valuable in obstetrics after delivery of the child and for the menstrual irregularity of the Menopause.

Prescribe 1 to 2 capsules 3 or 4 times daily. Supplied only in packages of 20 capsules. Literature on request.

As a safeguard against imposition the letters MHS are embossed on the inner surface of each capsule, visible only when the capsule is cut in half at seam as shown.

DOUBLY EFFECTIVE * * *

Relieves Nasal Congestion — Combats Infection

Metaphedrin Inhalant No. 99 (Abbott) contains the powerful antiseptic Metaphen, 1 part in 2,500, and Ephedrine alkaloid, 0.95%, in a light, bland mineral oil. Metaphen has been found to be 250 to 1,500 times more germicidal than phenol, depending upon the organism tested. In 1:2,500 dilution it is non-toxic, non-irritating to mucous surfaces and does not coagulate serum or tissue albumins. The chief value of Ephedrine lies in its power to decongest and shrink the nasal mucous membrane. This is accomplished with little or no irritation.

• This combination of antiseptic and

shrinking actions makes Metaphedrin Inhalant No. 99 an especially useful agent for the treatment of hypertrophic rhinitis, coryza, nasal and sinus infections, and the nasal congestion of hay fever. The product is of great value as a preventive of infection and is frequently used at the onset of certain cases to cut short the course of the disease itself. It is also valuable for instillation into infected sinuses and for use in all rhinological operative procedures. • Metaphedrin Inhalant No. 99 may be applied

topically or it may be prescribed as a spray. It is obtainable through pharmacies and is issued in ½-ounce, 1-ounce, 4-ounce and 16-ounce bottles. Enquiries for a free trial sample of Metaphedrin Inhalant No. 99 (Abbott) and for professional literature are welcomed. The coupon below is for your convenience.

Prescribing a Laxative

When, as frequently happens, the Physician is called upon to prescribe a laxative for prolonged personal use by the patient, Andrews Liver Salt merits special consideration. The main characteristics of this tonic laxative, listed below, suggest its wide range of suitability.

- 1 Andrews is pleasant-tasting. All ages take it readily.
- 2 Andrews causes none of the griping or other discomforts which often create reluctance to continue the use of the more drastic purgatives. Its laxative action is due to the presence of magnesium sulphate and other salts, which increase the fluid content of the bowel by Osmotic action, and so lead to painless, easy evacuation.
- 3 Because of its natural and non-habit-forming action, Andrews—in suitable doses—may be taken with every confidence by the physically weak and during pregnancy. This tonic laxative does not affect adversely the secretion of milk in nursing mothers. Indeed, the quantity of water taken with Andrews Liver Salt contributes to the extra liquids a nursing mother should take.
- 4 Andrews is particularly valuable in the case of patients liable to digestive trouble. The carbon dioxide which is liberated when Andrews is dissolved in water has a soothing effect on the stomach and a physical cleansing action on the stomach walls. Additionally, Andrews corrects excess acidity, stimulates the liver and promotes the flow of bile.
- 5 Andrews creates no dependence on artificial aid, but can be discontinued when the need for it ceases.

VOLUNTARY PARENTHOOD

Volpar is the new contraceptive formulated in co-operation with The Birth Control Investigation Committee of The National Birth Control Association. A report on the ten years exhaustive research which led to the production of Volpar appeared in The Lancet of October 15th, 1938, p.882.

The part played by The British Drug Houses Ltd. in this research, particularly in the production of 'a medium which would satisfy the clinical requirements of being spermicidally efficient to a high degree, completely harmless, æsthetically acceptable, and cheap,' was referred to in a letter (Lancet, October 22nd, 1938, p.970) signed by ten medical members of the said Committee.

It is stated further in the letter that the spermicidal power of the substance contained in Volpar is 'immensely greater' than that of those spermicidal substances '... that have been included in the numerous proprietary products which have been brought to the notice of the medical profession'.

Concentrated
Anti-Meningococcus
Serum (Group II)

(Globulin Solution)

The serum therapy of infections caused by group II organisms is often less successful than the specific treatment of group I infections due to types 1 and 3, which are usually associated with epidemics of cerebrospinal fever. Accordingly, a group II serum has been specially prepared at the Serum Department of the Lister Institute. This serum has been subjected to a process of concentration so that a large proportion of the inactive proteins has been removed; the dose of antibody is thus contained in a smaller volume of fluid.

Three preparations are issued in
concentrated form :

- (1) Anti-meningococcus serum (multivalent)
- (2) Anti-meningococcus serum (Group I)
- (3) Anti-meningococcus serum (Group II)

Anti-meningococcus Serum for Diagnostic Purposes

THE COMMON COLD

Controlled

RAPID RESPONSE TO DISSOLVED VACCINE G.L.

The advantages of Cold Dissolved Vaccine G.L. in prophylaxis of the common cold are twofold. Firstly, full dosage of the dissolved vaccine may be given from the beginning. The antigens are already freed for immediate utilisation. Immunity is thus developed much more rapidly.

Secondly, the period of immunity achieved, represents a very definite increase: the patient is protected for a reasonable and satisfying period. Natural susceptibility is, of course, an influencing factor, but in most instances a prophylactic course of Cold Dissolved Vaccine now, followed by 'refresher' injections in late winter, creates a persistent resistance and a positive immunity

lasting throughout the 'cold' season. The rapid anti-body response excited by Cold Dissolved Vaccine has an added value in treatment. A cold can often be aborted by prompt injection of 0.5 cc.

Whooping Cough.

It has been consistently demonstrated that Whooping Cough can be prevented or treated by dissolved vaccine. The effective dosage is 3 or 4 injections, 2 of 0.25 cc. and 1 or 2 of 0.5 cc. This course may be safely and painlessly given, even to young children. The Whooping-Cough Dissolved Vaccine G.L. induces prompt anti-body response without disabling or unpleasant reactions.

DISSOLVED VACCINE G.L.

In rubber-capped bottles: 5 cc. 7/6; 10 cc. 10/9; 25 cc. 17/6.

ULCERATIVE COLITIS: CLINICAL ASPECTS

by

E. R. CULLINAN, M.D., F.R.C.P.

Physician in Charge of Out-patients St Bartholomew's Hospital, Physician, Woolwich Memorial and Gordon Hospitals

Ulcerative colitis was described by Hale-White in 1888 and Allchin in 1885, and discovered at necropsy by Samuel Wilks in 1875. It seems to have been known to Sydenham, who in 1669 described the "bloody flux." Although the disease has definite clinical and anatomical features, there is still controversy about the symptoms and treatment, and the cause has remained particularly obscure. It was the purpose of the present investigation to see, by studying the clinical aspects of a fairly large series of cases of ulcerative colitis, whether fresh light could be thrown on any of these points. The material consisted of forty unselected cases of "idiopathic ulcerative colitis." One additional case in which the illness had started with dysentery many years previously was excluded for reasons which will be explained later. The clinical examination included a carefully dated life history. The appearances of the colon were studied with the sigmoidoscope. The stools and blood were examined. Whenever possible, radiographs were taken both by barium meal and by barium enema, and test meals were made.

Definition

In idiopathic ulcerative colitis there is severe inflammation of the mucosa and submucosa of the colon, generally with superficial ulceration. The deeper layers are rarely affected. Although the whole colon is often involved, the lesion almost without exception predominates in its lowest part, and also in the upper part of the rectum, the lower portion of which is often normal. Clinically the disease is characterized by the frequent passage from the bowels of blood, mucus, and often pus. It tends to pursue a chronic course lasting many years, marked by a succession of relapses and remissions. An attempt was made, by considering the features in each case, to divide the disease into three groups: those where the lesion is localized to the recto-sigmoid region (the so-called granular proctocolitis); those where it starts in the recto-sigmoid region but later becomes diffuse throughout the colon; and those where it is diffuse from the start. It was found that no such real distinction could be made. Not only are all gradations of the one disease process seen in different patients, but often the type appears to change in an individual patient.

Incidence

The disease is one of early adult life. The illness in the present series started between the ages of 11 and 20 in nine cases, and in twenty-one others between the ages of

21 and 30. The youngest was a girl of 10 and the oldest a man of 61. There were approximately twice as many women as men. The sex had no relation to the age of the onset or to the type or severity of the disease. Most of the patients were sedentary and not manual workers, and were of a higher educational standard than the average hospital class.

Onset of Disease

The onset may be insidious (fourteen cases), but is more often sudden (twenty-six cases). The first symptoms are usually diarrhoea and the passage of blood and mucus. Occasionally there is constipation. Of the forty cases the onset occurred with diarrhoea (thirteen with blood) in twenty-seven, constipation (six with blood) in seven, and normal bowel actions, with blood, in five. Another common symptom is pain in the lower abdomen, relieved by opening the bowels. Although the onset is often abrupt, the initial illness is seldom acute. Only two of the patients had fever. In spite of the diarrhoea and the passage of blood and mucus from the bowels, the general health often remains at first surprisingly good. More than half the patients did not seek medical advice during the first month of their illness and five waited over a year. When asked the reason for the delay they said it was because they had felt relatively well and had taken little notice of the state of their stools. It is a common experience to see patients who have not reached an acute stage and later, during remissions, passing the most horrible stools and yet remaining in apparently good health.

It has been said that ulcerative colitis sometimes results from mucous colitis. This is not our experience, either in this series or elsewhere. This agrees with the opinion of Spriggs (1934) and others. Mucous colitis is a syndrome, which incidentally one sees far less often than some years ago, associated with chronic constipation and the misuse of purgatives. The nature of the onset has no relation to the subsequent severity of the disease. The most banal beginnings can herald the most serious symptoms.

Symptoms

General Symptoms.—Either at the onset, or after a period of mild initial symptoms lasting for weeks or years, the patient may become gradually or quite suddenly extremely ill. Then, after an illness continuing perhaps for months, in which the patient sometimes becomes

almost moribund, there is a remission, with recovery. Again after an interval varying from weeks to years there may be a further relapse, and so on. The profound loss of weight and strength during a severe attack is one of the outstanding features of the disease. In spite of this, as was pointed out by Hardy and Bulmer (1933), there are few diseases in medicine in which a patient may reach such a stage of exhaustion and emaciation and yet rapidly make so spectacular a recovery. During a remission the patient may feel quite well. Although, as has been explained, it is not really possible to differentiate between the various forms of the disease, it may be said that when the lesion seems diffuse throughout the colon the illness is often more severe and is characterized by grave constitutional symptoms such as fever and rapid emaciation. On the other hand, when the disease appears to be localized mostly to the recto-sigmoid region (abnormal sigmoidoscopic appearances but normal radiographs) the illness is often of long duration, milder in degree, and marked more by anaemia from haemorrhage than by severe general symptoms.

Fever (seventeen cases).—In severe cases there is fever. It may be continuous or intermittent, and may last for weeks or months. It is always accompanied by a worsening of the patient's condition. It is seen more in the diffuse cases than in those where the lesion seems localized to the recto-sigmoid region.

Abdominal Pain.—Abdominal pain is a common symptom (twenty-five cases), but is seldom severe. It is of several types:

(a) Pain in the lower abdomen, which is often colicky. It gradually becomes worse before passing a motion, which relieves it. The pain may be worse when the patient moves about.

(b) A sensation of a lump in the rectum or pain in the lower part of the sacrum.

(c) A discomfort in the rectum, with a desire to open the bowels, but often not relieved by so doing. This symptom is seen particularly in cases where blood and mucus are passed many times a day without any faecal material.

(d) Tenesmus, is relatively uncommon, although the patient often has an unfinished sense, without pain, after passing a motion.

Other Gastro-intestinal Symptoms.—Flatulence, borborygmi, and a feeling of abdominal distension are common. During severe attacks there is often loss of appetite, nausea, and vomiting. Otherwise the appetite remains good.

Nervous Symptoms during the Course of the Disease.—It is an old saying that affections above the diaphragm tend to optimism and those below to pessimism. Ulcerative colitis is no exception. In severe cases there is marked prostration, depression, and anxiety. It is a matter of common clinical experience that the degree of this mental disturbance is related not only to the intensity of the physical disturbance but also to the previous personality of the patient. Although no clear distinction has commonly been made between the psychological characteristics and symptoms which precede and those which follow the bloody diarrhoea, those who have studied the condition have almost invariably noticed in these patients the presence of grossly abnormal mental symptoms. These points are discussed further in the following paper by Dr. Wittkower.

Bowels.—Diarrhoea is a common symptom. In some this is more marked after food and in others more in the morning and evening. Thirty patients in our series of forty stated spontaneously that emotional factors such as

startling events, anticipation of embarrassing situations, or even fear of the symptom brought on attacks of diarrhoea. There may be as many as forty stools a day. When the lesion appears to be affecting the whole colon the stools are frequent, offensive, fluid, thin, and soup-like, consisting of faecal material closely admixed with blood, mucus, and often pus. On the other hand, when the disease appears to be confined to the recto-sigmoid region, blood and lumps of blood-stained mucus and also pus may be passed many times a day separate from the motion or without any faecal material at all. Half the patients in this group were actually constipated, and although their bowels might be opened ten to fifteen times a day faeces would only be passed every second or third day. Ten of the forty cases in this series were constipated, although some of them had occasional attacks of diarrhoea. Nearly all the patients complained of urgency of defaecation. They all feared incontinence, but only five had any loss of control throughout the course of the disease.

Physical Signs

Considering the gravity of the disease the physical signs are slight. They are:

Abdomen.—The abdominal wall is often thin. Although there is a sense of fullness on palpation, visible distension is seldom seen. Occasionally there is retraction. Rigidity is rare. Tenderness, when present, is mostly in the lower part of the abdomen and along the course of the large bowel, particularly over the descending colon. The colon, usually the caecum or descending colon, was palpable in thirteen cases. The descending colon sometimes feels contracted and mobile.

Blood Pressure.—During the severe phase the blood pressure is often low, and the systolic pressure may be under 100.

Per Rectum.—The sphincter is often contracted, and digital examination painful to the patient. The mucous membrane may feel velvety and later rough.

Stools

Blood and mucus were always present in our series and pus less often. Frank pus is evidence of ulceration. The stools were carefully examined for parasites and organisms. Parasites and their products were never seen. Abnormal organisms were found in sixteen cases. They were thought to have little significance, as they differed from each other and belonged to types which are not normally pathogenic. They included *B. asiaticus*, *B. alkaligenes faecalis*, *B. lactis aerogenes*, and haemolytic *B. coli*, but were mostly unclassifiable non-lactose-fermenting coliform organisms of no known pathogenic group. Dysenteric organisms were never found. Anaerobic cultures for Bagen's coccus were seldom made, for reasons which will be later explained.

Blood

Most cases throughout the disease show a moderate anaemia, which becomes more marked during a relapse and recovers again with a remission. The anaemia tends to be greatest when the recto-sigmoid region is the part most affected. Only once did the haemoglobin fall below 40 per cent. The particular instance illustrates the great powers of recovery in the disease: the haemoglobin fell to 28 per cent. during a relapse and rose to 90 per cent. in the following remission. In half the cases there was no leucocytosis. During a severe relapse

the figure may rise to 12,000 or 15,000 per cmm., but only in one case was it ever higher than 20,000. The differential count is either essentially normal or shows an increase in polymorphonuclear cells when the total white count is raised. Gross eosinophilia was not noticed.

Sedimentation Rate.—This was examined in twenty-one cases. The highest recorded figure was 43 mm. in the hour (Westergren), but the average was 16 mm. Owing to the anaemia and loss of fluid these figures must be regarded as inaccurate. They are surprisingly low, however, if the disease be regarded as a primary infection.

Agglutinations.—Occasionally agglutinins to various organisms, including dysenteric organisms, are found in low and insignificant titre in the blood (for example, Flexner Y: 1 in 25). It is possible that they are produced by the secondary invasion of the ulcers in the colon by organisms which may have acquired mildly pathogenic qualities.

Sigmoidoscopic Appearances

The mucous membrane of the upper part of the rectum and the lower part of the sigmoid has a reddened granular appearance and bleeds easily wherever the instrument touches it. Blood and mucus are seen coming down from higher in the bowel. The condition was found without visible ulceration in eighteen cases. In others the mucous membrane is more oedematous, and superficial ulcers appear (seven cases) which at first are tiny but later run together and form larger ulcers, often covered with a mucus-purulent exudate. In more chronic cases there are callous ulcers with oedematous mucous membrane between. Less often the mucous membrane has a "cobblestone" appearance. During remissions healing ulcers may be observed with normal intervening mucous membrane, and in some there are linear or three-pointed scars of healed ulcers. It should be recognized that the presence or absence of visible ulceration bears no relation to the extent of the lesion or the severity of the disease. Furthermore, the mucous membrane is quite capable of healing. In two cases a perfectly normal mucosa was seen where previously there had been a granular appearance with superficial ulceration. Rectal strictures were observed in two cases of long standing.

X-ray Examination

Whenever possible, radiographs were taken before and after the evacuation of a barium enema and nine hours after the ingestion of a barium meal. The rectum is often small. The passage of the enema round the colon is sometimes very rapid, the barium reaching the caecum in twenty seconds and in some instances going a short way into the ileum. The caecum is often large and baggy. In mild stages of the disease, apart from this quick passage, there may be no other gross abnormality. The colon is usually irritable. Nine hours after a meal, in some cases, nearly all the barium will have been expelled, and in others, although the passage may be slow, parts of the colon will contain little barium.

The most characteristic feature is the complete lack of haustration seen in the distal part and sometimes in the whole colon. This tubular appearance is often found in mild cases, but if there is also narrowing the disease is usually severe. In such cases the bowel has a streaky appearance after evacuation. In parts of the bowel the outline may be spiky and irregular. When the disease is severe there may be a fine granular mottling of the bowel shadow and sometimes a moth-eaten, marbled effect, with numbers of translucent areas of various shapes

and sizes. The appearances alter in individual cases according to the stage of the disease. Thus in one instance the whole colon was irregular and streaky, and six months later, when the patient had improved, it was smooth and tubular.

Test Meals

Fractional test meals were taken in twenty-three cases. In five there was complete achlorhydria, in four slight hypochlorhydria, seven were normal, and seven showed a high content of free hydrochloric acid. These findings conform with those of Spriggs (1934) and Hurst (1935), and do not lend support to a theory that the disease is usually associated with acidity. However, four of the patients who had achlorhydria or gross hypochlorhydria showed, by radiographs or carmine, that food passed rapidly through the gastro-intestinal tract. In three of these a long period of diarrhoea had preceded the appearance of blood in the stools. It is an interesting speculation as to whether in these cases and some others the constant arrival in the colon of imperfectly digested food from higher up may give rise to a secondary colitis.

Evolution of the Disease

Ulcerative colitis pursues a chronic course, usually with a succession of relapses and remissions. The disease is of long duration. It had started more than a year ago in thirty-four of the cases, more than five years ago in thirteen, and more than ten years ago in nine. In one instance the disease had existed for thirty-four years. Twenty-eight of the forty patients had relapses, mild or severe. It is often thought that as time goes on the remissions become shorter and relapses more grave. This is not our experience. Remissions and relapses might last for days or years. The length of remissions was quite irregular, and bore no relation to the number or severity of previous relapses. Moreover, the severity of a relapse was not influenced by the length and severity of former ones. Of the twenty-eight patients who relapsed, twenty-three were well during their remissions—fourteen completely, six save for constipation, and three except for occasional diarrhoea. Others had looseness of the bowels with occasional blood in the stools, but otherwise remained in good health.

Causes of Relapse

It is generally recognized that a relapse may be brought on by an acute infection such as tonsillitis, an error of diet, a change in the weather, and so on. It is not, however, generally conceded that nervous factors play much part. Thus Hurst (1935) says that "relapses tend to occur with acute infections . . . and, much less frequently, fatigue from mental or physical overwork"; and Spriggs (1934) states: "In one patient any emotional stress at home would be followed by bleeding from the bowel." In our experience nervous factors play a large and important part in bringing about a relapse. This aspect will be dealt with later in greater detail, but it is interesting to record here those factors which the patients themselves considered responsible and how many times they regarded nervous factors as the cause.

Table showing Causes of Relapse according to the Patient

| Cases | | Cases | |
|-----------------------|---|---|----|
| Food indiscretion | 4 | Menstruation | 3 |
| Fruit | 4 | Menopause | 1 |
| Hot drinks | 1 | Emotional factors (shock, worry, anxiety) | 20 |
| Purgatives | 1 | Violent denial of emotional factors | 2 |
| "Colds" | 2 | | |
| Change of temperature | 2 | | |

Complications

The complications in this series were few, although I have seen most of them from time to time in other cases. The direct complications may be severe or fatal. Severe haemorrhage, perforation (rare and often difficult to diagnose), perirectal suppuration, polypoid conditions, strictures, and malignant change are well known. The more remote complications are arthritis, septicæmic conditions, severe lesions in the mouth, and eye troubles. In the present series pseudo-polypoid conditions in the large bowel were sometimes seen. Two cases had rectal strictures. Iritis was present in one. Occasionally there was ulceration of the mouth. Two had arthritis synchronous with the colitis. None of the cases showed any evidence of pyelitis or cystitis, which is in agreement with the findings of Ball (1926-7).

Diagnosis and Prognosis

The diagnosis is seldom difficult if the investigation is thorough. It cannot be stressed enough that all cases of chronic diarrhoea, and especially those with blood in the stools, must be thoroughly investigated. Apart from piles and fissure there are no mild causes of bright blood in the stools, and patients may often ascribe blood as coming from piles which in reality is coming from higher up. In the course of routine sigmoidoscopy we have recently seen two operable malignant new growths, one in a woman thought to be suffering only from simple mucous colitis.

The prognosis of an individual case is difficult to assess, and must of course be reserved. We believe that it is not nearly so serious as regards life as is generally supposed. As has been said, there are few diseases in which a patient may become so ill and emaciated and yet recover. The number and severity of previous relapses has little relation to the prognosis. Hospital wards give an exaggerated idea of the gravity of the condition, as only the severe cases are seen. Many of the cases are much milder than these, particularly when the lesion appears to be localized to the recto-sigmoid region rather than diffused throughout the colon. At the present time all the patients in this series are alive and most of them in moderately good health. Some—and these include cases which have been very severe—seem almost to have recovered. Among the milder cases there was one woman who had had the disease for fifteen years. During all this time she had had diarrhoea, with occasional blood in the stools. Six months ago the diarrhoea stopped and she has been perfectly well since. However, complete recovery from the disease with no liability to future breakdown is probably uncommon.

Pathogenesis

As to the cause of this disease many theories have been advanced but none is satisfactory. In the present series only one patient admitted to a dietary indiscretion at the time of the onset. There was no evidence of lack of vitamins, of focal sepsis, or of allergic response. There was nothing important in the past or in the family histories, except that as children the patients did not appear to have been strong. Eight tended to have diarrhoea, four of them whenever nervous, and seven tended to be constipated, but there was seldom any history of long-standing diarrhoea or constipation preceding the disease. Only nine of twenty-three patients tested had subacidity of the gastric juice. Only one had a previous rectal lesion—a perianal abscess ten months before.

There is no convincing evidence that the disease is the result of a primary infection of the colon. Neither the histological findings nor the clinical picture suggest it. No proved organism has been found. Bargén's coccus may be present in the ulcers, but it is not generally accepted that this organism is responsible for the disease. It appears to be a normal inhabitant of the bowel. Professor Garrod (1938) tells me that he found it not only in the stools of eleven out of seventeen patients with ulcerative colitis but also in the normal stools of fourteen out of twenty-six people not suffering from the disease. It is said that when obtained from the ulcers this organism is capable of producing a colitis when injected into rabbits; but this applies to other organisms similarly obtained, such as those described by Buttiaux and Sévin (1931), and Gallart-Mones and Sanjuan Domingo (1935). The probable explanation is that Bargén's coccus and other normal organisms enter the ulcers as secondary invaders. It is of course possible, when secondary invasion has taken place, that organisms which are normally benign may acquire more pathogenic qualities and still further add to the existing inflammation. Another argument advanced in favour of Bargén's coccus is the response of the patient to specific treatment. This is no guide as to the specificity of the organism, as it will be shown later that a wide variety of treatments can produce admirable results in the same patient.

There is considerable evidence that these cases were not caused by dysentery. One case of proved dysentery was deliberately excluded from the series. The disease was not contagious, infectious, or epidemic. It often began insidiously without fever. There was no history of dysentery in the past. Only four of the patients had ever left the country—three to the Continent and one to Palestine to recoup from a relapse of her colitis. Only three patients related that other members of the family had ever had bloody diarrhoea. The organisms were never found in the stools, though carefully looked for. Hurst (1935) suggests that dysentery bacilli are seldom found, as the cases are already chronic when the stools are first examined. I saw two patients, however, one week and three weeks from the onset of their symptoms, and in neither of these was Professor Garrod, after repeated examination, able to demonstrate the organisms in the stools. We believe that the reason so much stress has been laid on dysentery as a causative factor has been that many of the published series of cases were near the time of the great war, when dysentery was so common. The patients in the present series, however, had not had war experience, having mostly been too young. If the disease were due to dysentery the history should be easy, the organism should be found in early cases, and the disease would be more widespread.

For a long time I had a growing conviction that, apart from the nervous symptoms developed in the course of the disease, emotional disturbances superimposed on an unusual or abnormal personality frequently preceded the onset. For this reason I asked Dr. Wittkower to examine the emotional background of these patients. As this aspect of the disease is unfamiliar his findings are given in some detail in the paper which follows. The results are interesting. He states that in thirty-seven of the forty patients psychological abnormalities, well beyond the range of individual differences of the average population, antedated the colitis, and, further, that in twenty-eight cases clear-cut emotional trauma, serious enough to be regarded as a precipitating agent, immediately preceded the onset of the disease.

To summarize: while not suggesting that an emotional upset is the sole cause of the disease (it is not), we do suggest that it is a most important factor in the aetiology. The mechanism remains obscure. It may be that with these people the bowel is particularly prone to the lesion, and that a similar emotional disturbance in others would produce, perhaps, simple diarrhoea. Once the disease is established, invasion of the mucosa by organisms secondary to the ulceration still further complicates the picture.

Treatment

Nearly all patients with ulcerative colitis, even when they appear almost moribund, will respond well to careful treatment. It is fair to say that no specific therapy has as yet been devised. The success of a particular remedy is no proof of its specificity. Individual patients may respond in an astonishing way to many and varied treatments, and it seems that suggestion plays a large part in their success. There are many examples in the present series, but a few will serve as an illustration.

Case 1.—First attack; recovery with general treatment. Second attack (very severe, and patient almost moribund). "During moments of consciousness the Rabbi came to see me and told me that I was being very selfish and making my parents ill. It was then that I wanted to get better and really did get better." Weight went up three stone. Third attack (following a mental upset): Recovery with appendicostomy. Now keeps well by passing catheter into the opening.

Case 2.—Recovered from six attacks. The first with general treatment; the second with wash-outs; the third with wash-outs and iron; the fourth with serum; the fifth with autogenous vaccine; the last with general treatment.

Case 3.—Recovery followed operation for a hernia.

Case 4.—First attack relieved by an appendicostomy; the second by reopening it; the third by stopping the appendicostomy wash-outs; the fourth and fifth by general treatment.

Symptomatic Treatment

Various treatments were used with these patients, but the following seem to us the important points:

1. Rest in bed and warmth whenever there is fever or general illness.
2. In the acute stage the diet should be bland and simple, but later, although it is important that it should have a low residue, the diet should be nourishing and high in caloric value. Seasoned foods, spices, and hot or effervescent drinks should be avoided. Large quantities of milk are seldom well borne.
3. Vitamins should be added to the diet—for example, radiostoleum (10 minims twice a day), marmite, and orange juice, or, if preferred, ascorbic acid (100 mg. a day) by mouth.
4. Iron should be given for the anaemia. Even in large doses by mouth it seldom seems to aggravate the condition of the bowel. Thirty grains of ferri et ammon. cit. thrice daily or dry ferrous salts are useful. Iron combined with liver, as in some of the proprietary capsules, is often valuable.
5. Adsorbents such as kaolin, kaylene-ol, lacteol, and charcoal are given when the stools are offensive. Two or three teaspoonfuls of "carbantren" (composed of iodochloroxyquinoline-bismuth 10 grammes, pectin 20 grammes, active charcoal 70 grammes) may be administered twice a day in water. We have given this preparation an extensive trial and are pleased with the results.
6. Wash-outs should be used with caution; they often do more harm than good. When there is much pus in the stools saline wash-outs gently given may occasionally be of value. When there is much haemorrhage from a "weeping" mucous membrane 0.5 per cent. tannic acid may be used.

7. Atropine or tincture of belladonna may be given when there is spasm of the colon. Opium may be necessary, but should, if possible, be avoided. When there is achlorhydria, half a drachm of dilute hydrochloric acid made up in half a pint of orange drink may be sipped slowly with meals. In the less acute stages patients should be given general tonics such as strychnine and glycerophosphates.

8. Two special measures, as part of the general treatment, are sometimes of considerable value:

(a) **The Raw Apple Diet.**—The patient is given twelve pounded raw apples without core, pips, or skin each day with a little water to drink but nothing else to eat. This is continued for several days. It often greatly improves the stools, and any improvement will show itself within two days.

(b) **Cod-liver Oil Retention Enema.**—At the end of the day 4 oz. of crude cod-liver oil are injected slowly and gently into the rectum. The patient wears a towel and retains the oil, if possible, throughout the night. Best (1938) advises that a 20-oz. normal saline enema should precede the injection. When the saline has been expelled the oil should be run in with the patient in the knee-chest position. The treatment may be continued daily, or on alternate days, for a period of three to six weeks.

9. Agar, normocol, and isogel are sometimes helpful in giving bulk to the stools.

10. Patients who are constipated should take liquid paraffin indefinitely.

11. Blood transfusions are not only of great value as an emergency measure when there is severe anaemia, but also small transfusions (250 c.cm.) serve as useful tonics during the more severe phases of the disease.

12. Of the various surgical treatments, ileostomy seems to us the rational operation. Only by this operation can the colon be put at complete rest. The decision, however, should be made with great care, for not only do the most severely ill patients frequently recover with careful medical treatment but the mortality from this operation is probably still in the region of 50 per cent.

Dr. Wittkower's results suggest that selected cases might be amenable to psychotherapy. Two patients who had had the disease for many years practically recovered after relating the story of their difficulties.

In conclusion, it may be said that the secrets of successful treatment depend upon the meticulous consideration and care of each individual patient, the symptoms being treated as they arise. Specific methods have been successful in the hands of enthusiasts and less so in the hands of others, and this implies that suggestion plays a powerful part in the remission of the disease. An optimistic attitude is essential, and it is necessary that both the doctor and the patient should have complete faith in the efficacy of the treatment.

Summary

The clinical aspects of forty unselected cases of idiopathic ulcerative colitis have been studied.

The lesion is nearly always greatest at the recto-sigmoid region, and no sharp distinction can be made between those cases in which it is localized to this region and those in which it is diffused throughout the colon.

The disease mostly affects sedentary workers under the age of 30—women more than men.

The onset may be mild or severe. The disease does not follow mucous colitis.

The symptoms and signs are described. When the lesion is diffuse there is often severe illness, with fever and emaciation; when the lesion is localized the disease tends to be milder and characterized more by anaemia

from haemorrhage. In the latter type constipation is not uncommon.

Pathogenic organisms were never found in the stools.

The blood picture is discussed.

The sigmoidoscopic appearances of the bowel are recorded. The presence or absence of visible ulceration bears little relation to the severity or the extent of the disease. Healing is sometimes observed.

The radiological appearances are characteristic. The passage of a barium enema throughout the colon is usually rapid: the rectum is small. Lack of haustration in the colon may be seen in mild cases; if there is also narrowing the disease is usually severe. Other appearances in severe cases, such as fine granular mottling or "marbling," are discussed.

Achlorhydria is infrequent. It is possible that very occasionally the colitis may be secondary to achlorhydria and the rapid passage of food through the stomach and small intestine.

The disease runs a chronic course, with remissions and relapses. The relapses occur at irregular intervals and bear no relation in their severity or duration to previous ones. They are often precipitated by emotional traumata.

Complications in this series were few.

Diagnosis is not difficult if all patients who are passing blood in the stools are thoroughly examined.

Prognosis must be reserved; but the disease is not so serious as regards life as is generally supposed. Occasionally there is complete healing of the lesion.

The pathogenesis is discussed. Although it is obvious that there is secondary infection of the colon, evidence that the disease is caused by a primary infection is unconvincing. While not suggesting that an emotional upset is the sole cause of the disease, it is suggested that this is a most important factor in the aetiology.

Methods of treatment are described. Meticulous care of each patient and an optimistic attitude on the part of both patient and physician are essential.

I am grateful to Professor Garrod, Mr. Naunton Morgan, and Dr. J. V. Sparks for their aid in a number of the examinations of the stools, the sigmoidoscopies, and the radiographs. Some of the patients were under the care of my colleagues at St. Bartholomew's and the Woolwich Memorial and Gordon Hospitals, and we thank them for their courtesy in allowing us to examine these patients.

ULCERATIVE COLITIS: PERSONALITY STUDIES

BY

ERICH WITTKOWER, M.D. Berlin, L.R.C.P. Ed.

Halley Stewart Research Fellow and Assistant Physician to the Tavistock Clinic; Clinical Assistant at the Out-patient and Psychological Department, St. Bartholomew's Hospital

In continuation of previous psychosomatic researches, I gladly accepted the invitation of Dr. E. R. Cullinan of St. Bartholomew's Hospital to investigate the relative significance of physical and personality factors in what is known as ulcerative colitis.

Ulcerative colitis is a comparatively rare disease, characterized by bloody diarrhoea, with a typical proctoscopic and x-ray picture. There is a tendency to relapse and remit, and a bad prognosis; in contrast to dysentery, ulcerative colitis has been described as "non-specific" colitis. It was chosen for the present study because such patients commonly refer its onset and relapses to "worry," and often appear mentally abnormal even to the casual observer.

Material and Method of Examination

A biographical study was made of forty unselected patients with ulcerative colitis, physically examined by Dr. Cullinan. Usually the patients were submitted to two or three interviews, each of two or three hours' duration. If necessary, the data were checked by an objective anamnesis, obtained from relatives. A detailed report on each patient has been kept available. The ages of the patients at the time of examination were from 12 to 65, the onset mainly between 20 and 40. Fifteen were men, twenty-six women. As compared with the average hospital class, they were better educated.

Findings

In the majority of the patients studied psychological abnormalities and disorders far beyond the range of individual differences in the average population were found to antedate the initial onset of the colitis. In relation to other investigations control groups of patients have been examined by methods which are identical with those used in the present research. In the ulcerative colitis patients the degree of difference from average individuals was so gross as to make a special control group unnecessary. A dated clinical history and a dated life history, taken independently and verified from relatives, showed that disturbing events in the patient's life had preceded the onset, return, and increase of symptoms more often than can be due to chance.

Personality of Patients suffering from Ulcerative Colitis

CHILDHOOD ADJUSTMENT

As will be shown below, in their characteristics as children these patients showed clearly psychological patterns which in adult life became intensified to an unmistakably abnormal degree. The patients did not fall into any one psychological group. An attempt was made to clarify the diverse symptoms present by a study of the childhood characteristics, since these might be expected to be simpler. As these at first sight showed no obvious common factors a simple statistical approach was used. A chart was prepared on which was marked

for each patient the presence or absence of thirty-seven numbered character traits. The columns were numbered and not named after character traits and mathematical examination allowed an unbiased division of the patients into certain groups. Selecting a column obviously belonging to a frequent characteristic this was repeatedly correlated with columns indicating other characteristics. Three groups of associated characteristics slowly emerged. On decoding these from numbers to the character traits, they signified the groups to be as follows:

Group I.—This group comprises seventeen patients who had described themselves as over-conscientious and/or over-scrupulous children. Correlated with this more than ten were shy, timid, over-sensitive, and withdrawn. They shunned games and parties and preferred reading. At school they worked very hard, were exceedingly ambitious, and worried unduly about their achievements. They were accurate, reliable, clean, and tidy. A fair number stressed spontaneously their horror of dirt. The following abstracts may illustrate some of these features:

C. H.; 12 years old.—Mother's report: "Connie is very clean and tidy in her habits and very conscientious and extremely ambitious in her school work. She cannot bear to see anyone better than herself. If there was someone better, she used to say: 'I do want to beat her.' She is prone to under-estimate her own abilities. At school she always used to wonder if she would pass her examinations. Connie is not a very good mixer. She would rather read than play; it has always been difficult to get her out to play."

Group II.—Twelve patients described themselves as excitable in childhood. Seven of these were obstinate, stubborn, argumentative, cantankerous, and overtly aggressive. In general they were jolly, happy-go-lucky, and did not care very much about their appearance or achievements. At school they were often noisy and up to mischief—frequently the dread of their teachers. In contrast to Group I, they had "heaps" of friends, liked to perform, and enjoyed "showing off." They were prone to display their emotions and apt to produce explosive affects when frustrated. A typical instance is given in the following:

A. S.; 23 years old.—"From the day I was born until I was over a year old I never stopped crying. Later on I was obstinate, argumentative, quarrelsome, always up to mischief, always getting into trouble. I ran up and down stairs and made a terrible noise to annoy the others. At school I was a great nuisance. I was inattentive, fidgety, and used to talk when I was not supposed to, and would whisper, giggle, throw notes, or eat sweets during lessons. I hated going to school, and made many excuses to stay away. Often I pretended to be ill or deliberately hurt myself to find an excuse."

Group III.—This group embraces six cases. Their common characteristics were their quiet, unassuming, accommodating behaviour in childhood. They were polite, courteous, and respectful, and extremely anxious not to hurt anybody's feelings. They kept in the background as much as possible and blushed on the slightest occasion. Their feeling of inferiority prevented them from association with other children. They were apt to take offence easily, and would brood over an often imaginary slight for days without showing it outwardly. The group is typified by the following example:

L. S.; 34 years old.—This patient was shy and retiring as a child. She never liked going to parties and felt uncomfortable with a lot of other children. She always let others go first: she preferred to keep back, and if she was called in front of others she would go red. If anyone said anything harsh to her she would brood over it for days.

There remained five cases of the total which did not fit in with any of the above three groups, and which are here classed as Group IV.

ADULT ADJUSTMENT

In the patients as adults, the groups seen in childhood remained unchanged in composition and often showed an accentuation of the differentiating characteristics.

As adults, the majority of patients in Group I were energetic and efficient. Their facial expression was often hard, determined, tense, and sometimes drawn, sullen, and dissatisfied. As a result of unreasonable feelings of inferiority and an acute sense of their obligations, their sole aim in life was to achieve safety and security, working long hours and finding it difficult to relax during their rare holidays. Despite this they were often dissatisfied with their achievements. Reliable and over-conscientious, they were always anxious to set an example, and tended to expect from others the same standards as they set for themselves. Most commonly they were over-careful with money and unable even to owe "a penny"; a few were foolishly generous or oscillated between these two attitudes.

Their attitude to religion and sexuality was unusually stern and rigid, and lapses, whether trivial or severe, brought disproportionate and prolonged feeling of guilt. Metaphysical problems similarly appealed strongly to them. Their high principles could be seen in their dogmatism, tectotalism, and their abhorrence of bad language and the "dirty" joke.

Over-orderedly, they liked everything to be done by method and could not bear to see things out of place. They were careful about their belongings and apt to keep things of little value. Thus a 52-year-old patient still kept his toys and school books, "which contained material which is very well written and spelled." They were sticklers for punctuality, and often arrived unnecessarily early for appointments in case they might be late. The majority were unusually neat, clean, and tidy in their appearance even if this strained their finances. Characteristically, one man, a clerk, invariably polished his boots whenever he went into his house. On the other hand, two of them were definitely dirty by any standards. Two others conspicuously broke down at one point by wearing a dirty collar or through dirty finger-nails.

A common feature of all members of the group was a failure to express emotion. They "bottle up" emotions and "worry inwardly." In their rare emotional moments by far the commonest feeling expressed was anger. As a result, in their social relations they were unable to adapt themselves to others and tended to live for the most part in a world of their own. Some were shy, timid, and self-contained. They disliked social gatherings, preferring reading or sitting in a corner and thinking about the conditions of the world. Others were resentful, obstinately sullen, or openly defiant. They were self-willed, and unable to admit that they were wrong. "I stick to my guns," a patient told us, "even if I think the other is right."

Grossly abnormal attachment to one parent was common. Considering their age and income, relatively few were married. In any case, their moral code was of such a nature as to interfere with normal sexual functioning, in many cases even to the point of sexual disorders.

Fourteen out of the seventeen members of this group displayed certain features which are grossly pathological—obsessional thoughts, fears, impulses, and actions. In

three cases these characteristics were floridly displayed as a severe obsessional neurosis which had been treated in a mental institution, a split schizoid personality and a schizophrenia with hallucinations and paranoid ideas.

Group II—made up entirely of women—by contrast consists of patients who are well in touch with reality, less harassed by conscience conflicts, and apt to display freely their stormy and transient feelings. They react emotionally with disproportionate intensity even to trivial situations, are impulsive, impatient, and moody, oscillate in rapid succession between moods of gaiety and despair, and may burst into tears or uncontrollable fits of laughter without obvious reason. Under hospital conditions most of them are noisy, petulant, and argumentative; incapable of falling in with the routine and unable to get on with the other patients. In their descriptions they tend to be theatrical, and their long and eventful life-histories abound in dramatic incidents in which they usually play a heroic part. Often they recite rather than give an account of their life-history. They often look younger than their age and are sometimes babyish in their speech and mannerisms. A woman of 23 wore a baby-ribbon in her hair and had a doll sitting by the bedside.

Like Group I, they were clean and neat, but by contrast they were often dressed loudly or were overdressed. They were anxious to attract the examiner; this was exemplified in one patient who at three interviews on three successive days wore three different nightdresses, without other justification. They wish to attract attention and to be cared for, praised, and spoilt. They are apt to magnify minor physical ailments, are prone to alarm those around them, and tend to make accusations of wilful neglect if they do not receive the amount of sympathy they demand.

More than usual the patients are suggestible both before and during their disease, as may be seen from an instance where one patient completely failed to improve in a hospital in which she complained that she was not being taken care of enough; in the second hospital, of which she said that "they were very much nicer," she showed a temporary loss of her diarrhoea, beginning on the day of admission. Another patient, who was thought to be *in extremis*, rallied and temporarily lost her symptoms when the rabbi pointed out that she was alarming her parents.

Superficial and labile in their interests, these patients are relatively inefficient in their occupations. They mix easily, but have acquaintances rather than friends. Over-enthusiastic friendships may turn into bitter enmity from one day to another. They enjoy social life so long as they dominate the stage. Violent fits of temper and numerous conversion symptoms are a common response to frustrations.

In their relations with men they have "heaps of admirers," but are incapable of loving deeply as a result of their own deep love of themselves. Their married life as a rule is stormy. On the surface, in comparison with Group I, their sexual activities in the narrow sense appear relatively normal; close inspection, however, reveals immature features and often an absence of deep interest or satisfaction. As one patient remarked, "I am in love with the sex and not with the man." Undue attachment to one parent, often openly ambivalent in its nature, is even more common than in Group I. Five out of the twelve members of the group displayed gross hysterical symptoms, such as hysterical abasia, astasia, shaking fits, shell-shock, screaming fits, hysterical vomiting, etc.

Group III comprised individuals whose psychological abnormalities were most obvious as social anxiety. Five out of the six in this group were shy, quiet, and depressed in their manner, and almost terrified of transgressing the rules of social behaviour. Without exception all of them gave a history of severe and lifelong difficulties, particularly in relation to their family, finance, and work.

Group IV was made up by the residue—five patients not falling into any of the other three groups.

To sum up, it has been shown that in thirty-seven of the forty patients studied the colitis was antedated by psychological abnormalities or definite psychological disorders well beyond the range of the normal. No uniform personality type could be established. Among the various psychopathological structures observed, two well-defined main groups—Groups I and II—are prominent.

The Emotional Factor

Further investigation concerned the importance of disturbing events in the patients' life-histories in relation to the onset, increase, and return of symptoms. Physicians familiar with the disorder unanimously agree that "excitement and worry" often bring on attacks of diarrhoea. Twenty-eight out of the forty patients examined reported relapses of their disease. In seventeen of these twenty-eight patients one or more relapses coincided with disturbances in their lives. Frequently each relapse of an individual case was connected with some external event, as in the case of a woman who had her first attack of colitis during a period of severe financial stress, when her husband, a drunkard, was out of work; her second attack when he got into serious debt; her third attack when he blackmailed her and robbed her of all her savings; the fourth attack when she discovered that he had been unfaithful to her; and the fifth when he left her for good under very distressing circumstances. Sometimes the patients notice a decline of their mental symptoms during the period of their increased bodily symptoms.

In twenty-eight out of our series of forty patients a clear-cut emotional trauma, serious enough to be regarded as a precipitating agent, immediately preceded the onset of the colitis. In eleven cases acute, in seventeen cases prolonged, emotional stress ushered in the disease. The remaining twelve contained on the one hand the most severe cases of psychological disorders, and, on the other, patients in whom no precipitating situations were to be found—through lack of co-operation, through failure of the interview method, or through genuine absence of an emotional disturbance.

In seven cases serious occupational difficulties, in four cases severe financial stress, preceded the onset of the colitis. Two patients broke down under the strain of a forthcoming examination. In six cases domestic difficulties and in two cases highly dramatic love affairs had a precipitating effect. Sexual conflicts of a grossly immature type played an important part in four cases. In three patients the colitis started in the course of pregnancy; in one of them obviously in relation to fear of labour.

As might be expected, internal precipitating conflicts were predominantly found in Group I, whereas dramatic external events prevailed in Group II. Precipitating disturbances related to self-preservation and security showed in Group II. Problems of personal relations and sexuality were in marked excess in Group II. The sexual problems of Group I were of an infantile type—for instance, excess-

sive masturbation guilt; and of an adult type in Group II—for instance, fear of labour. A few examples may illustrate the precipitating life situations.

1. A policeman, aged 48, a typical member of Group I, over-conscientious, over-scrupulous, over-ill, and with obsessional doubts, got into a panic during his last year in the police force. "It was always on my mind whether I should manage to carry through and get my pension—whether he would do something wrong and get caught or whether he would get into trouble and not get his full pension. During his last six months in the police force, at the peak of his anxiety, he had bloody diarrhoea.

2. A typist of 20, timorous, emotional, and broody since early childhood, had a severe nervous breakdown before her matriculation, with fear of insanity, fear of failure, fear of dying, free floating anxiety. She sat for the examination but failed. Six months later she tried it again. I still felt frightened; I was always conscious of myself that I was there. I was always with myself, always thinking about myself, nervous of myself." This time she passed her matriculation, but at the time she heard the result she had her first attack of bloody diarrhoea.

3. An addressograph operator, aged 36, a shut-in spinster, over-conscientious, over-clean, over-tidy, manifestly over-attached to her mother, developed a number of nervous symptoms—depression, crying fits, etc.—when, for the first time in his life, her father was taken seriously ill at Christmas, 1933. "In February, 1934, in the middle of the night, they rang us up from the hospital and told us that father was worse, and when we got there he was very ill. The next day I felt shaky and worked up to a pitch. In the course of the day very violent bloody diarrhoea started." A week afterwards she was admitted to the same hospital as her father.

4. A secretary, aged 25, available, pleasure-loving, fond of showing off, fell in love with her chief when she was 18. He was a ladies' man, and took advantage of her. Another girl appeared on the scene, and three months later he told her he was going to marry this other woman. "Immediately my inside turned over and I had diarrhoea." Tormented by jealousy, she continued to work for the man, but some months later married a man she did not love. Her husband went abroad and her jealousy slowly increased; at the peak of her resentment bloody diarrhoea set in. The onset of her severe symptoms waning from her former lover's sympathy, a confession of love, and blood for a transfusion. "It was a great sacrifice for him. I am sure that his blood did me more good than anybody else's, because I loved him and I felt I would like to have his blood in me."

The Precipitating Life Situation in Relation to the Total Personality

Similar precipitating events would not lead to this symptom in other individuals. Personality factors, somatic as well as psychological, are likely to predispose to the intensity and nature of the psychosomatic disturbance in emotional reactions. This may be illustrated by the more detailed history of a case.

When this patient was 2 years old his father deserted his mother, who went as a companion-nurse. He saw her only in the holidays, and lived with a foster-father, a narrow intolerant man of very strict religious principles.

The patient, a strong and healthy boy, was quiet, shy, and retiring, preferring to read and study nature. He took a special interest in the obvious methods of reproduction in flowers. "I was interested in the make-up of everything. I was never satisfied with being told that a thing was so. Many a time I was told I was born with a question mark in my mouth." He was afraid of transgressing the family code.

At school he was a fair scholar, enjoyed sport, and if chosen for a team felt unduly conscious of what was expected of him. He might have two or three motions on the day of a race. "A little time before I was ill we were swimming without

clothes, and were surprised by some girls who were rowing and who laughed and treated it all as a joke. I was very disturbed, and some little time after I had an urge to expose myself. I knew many suitable places. When a girl passed I made no attempt to cover myself. Almost without exception after each exposure I had attacks of bloody diarrhoea. I recollected the things I was taught and I had a natural understanding that I shouldn't do it. I think that the mental side gave me the pleasure of a feeling of well-being and at the same time gave me a mental punishment which took the form of upsetting the nerves. I think that the feeling of guilt has caused the colitis. I feel quite confident, in myself, that if I could get out of the tangle the physical side would respond to treatment."

Comments and Conclusions

Evidence has been given to demonstrate that ulcerative colitis is a disease of the mentally ill or maladjusted. Almost all the patients showed character disorders, obvious neuroses, or psychoses. As will have been recognized from the description above, Group I, characterized by over-conscientiousness, over-scrupulousness, orderliness, cleanliness, obstinacy, etc., was made up of obsessionals; Group II, characterized by emotional lability, temper tantrums, childishness, self-centredness, and suggestibility, consisted of hysterics, whereas Group III, less well defined than the others, contained some schizothymes and depressives. The classification in groups was less rigid than might appear from the description. Groups I and II overlap considerably. More than half the patients examined displayed well-marked obsessional characteristics; in more than two-thirds signs of a psychosexual immaturity were present. The precipitating conflict situations, although fairly uniform within the various groups, showed no universally common similarities.

If we assess the relative significance of somatic and psychological factors in the aetiology of ulcerative colitis very little can be said in favour of a primary bacteriological or dietetic origin. Numerous micro-organisms, Bagen's diplococcus, virulent *coli* bacilli, streptococci, dysentery bacilli, and many others have been suspected as aetiological factors. This aspect has been dealt with in the previous paper by Dr. Cullinan, and, as has been shown, the bacteriological origin could not be substantiated. With most observers, we regard the infection as secondary to ulceration. Among the various factors suggested as possibly of aetiological importance, in our observations the psychological factor seemed the most constant.

The relevant literature is scanty. C. D. Murray, Sullivan, Chandler, and others in a comparatively small number of cases discovered an "amazingly close chronological association between emotional episodes and the onset of bloody diarrhoea." Very few cases of ulcerative colitis have been submitted to psycho-analytical examination. Murray's case—the only one reported in some detail—was that of a woman who showed warping of her emotional development. Similarly, on examination of a number of patients with so-called spastic colitis, persistence of an infantile attitude and pattern of behaviour could be discovered (Alexander, 1934; Bell, 1933; Daniels, 1934; Levine, 1934; Wilson, 1934). In the presence of severe external difficulties the infantile attitude of these patients developed a greatly increased prominence as an expression of their resentment against an environment which they felt had betrayed them (Sullivan). Alexander studied six such patients, contrasting their surface attitudes with those of the deep unrecognized background. Among the latter are commonly found strong demanding and possessive tendencies incompatible with the ideals of the individual, producing deep unrecognized guilt which has led to

diarrhoea; the diarrhoea could be shown to have expiatory value. As well as satisfying an unrecognized need for restitution, the diarrhoea was observed to be used as an expression of hate. Alexander reports his findings with a reserve as to the general validity of his observations. Whether this same deep pattern applies to ulcerative colitis is unknown at the present stage; if so, a comparative study of spastic and ulcerative colitis should reveal an even more intense conflict situation and strong masochistic components in the latter.

The riddle of the aetiology of ulcerative colitis is still far from being solved. The psychological background described is not necessarily the cause of the obscure disorder, but is certainly an important aetiological factor in this severe organic disease. Many problems in relation to the physical and psychological aspects of the disorder await discovery.

Summary

1. A series of forty unselected patients suffering from ulcerative colitis was submitted to psychological examination. In thirty-seven of the forty patients studied the colitis was antedated by psychological abnormalities or definite psychological disorders well beyond the range of the normal.

2. No uniform personality type could be established. Among the various psychopathological structures observed, obsessional and hysterics were prominent.

3. The emotional factor as precipitating onset, relapses, and individual attacks of ulcerative colitis was examined in relation to the personality affected.

4. These findings appear to justify an attempt at psychotherapy for selected early cases of ulcerative colitis.

This investigation has been conducted during the tenure of a Fellowship endowed by the Sir Hailey Stewart Trust, to whom I am grateful for the opportunity. The access to cases has been arranged through Dr. E. R. Cullinan, to whom I am deeply indebted for the co-operation which has made this investigation possible.

G. Olin (*Bull. Off. internat. d'Hyg. publ.*, 1938, 30, 2230) records an epidemic of 115 cases of tularaemia which broke out in Sweden in July, 1937, and continued until the following October, the peak being reached at the end of August and beginning of September. Apart from the fact that there were only five cases under 10, all ages up to 70 were almost equally represented. Fifty were in males and sixty-five in females. The following types of the disease were noted: ulcero-glandular, 101; glandular, nine; oculo-glandular, one; and typhoid, four. The primary lesion was situated on the lower extremities in fifty-seven, on the upper extremities in fifteen, and on the face and neck in twenty-five cases. With a few exceptions the diagnosis was established by serological examination. In 107 cases there was a positive agglutination reaction for *B. tularensis*, in three this organism was grown from the primary or the glandular abscess, and in the remainder the diagnosis was made by the typical clinical picture. As in the two previous epidemics of tularaemia in Sweden, the outbreak was preceded by an epizootic among hares and other rodents.

APICAL BRONCHOGENIC CARCINOMA

 Smithdown Road

The early clinical manifestations of primary carcinoma of the lung are notoriously protean, ranging as they do from local signs of bronchiectasis or pleural effusion to cerebral tumour. These variations of behaviour depend to a certain extent upon the precise anatomical site of origin of the carcinoma, and of recent years attention has been drawn to the peculiarities of those arising in the periphery and, in particular, at the apex of the lung. We have seen several cases of this kind lately, and because of the conflicting views expressed in the literature concerning them we feel justified in presenting and discussing our findings.

In 1924 Pancoast reported four cases of tumour in the region between the root of the neck and the apex of the lung in which there was a peculiar clinical syndrome resulting from involvement of the brachial plexus and of the sympathetic cervical chain. This comprised motor and sensory disturbances in the shoulder and arm of the affected side, atrophy of the hand muscles, and Horner's syndrome—unilateral miosis, ptosis of the eyelid, enophthalmos, and anidrosis of the face and neck. In 1932 Pancoast republished these cases, added four others, and propounded the theory that the tumours arose from embryonal rests in the fifth pharyngeal pouch. He gave them the name of "superior pulmonary sulcus tumour," and claimed that they could be recognized radiologically, since they produced sharply defined shadows at the apex of the lung, destruction of one or more of the upper three ribs posteriorly, and some erosion of the transverse processes and bodies of the corresponding vertebrae. Pancoast's theory was based upon no more than two brief histological reports on biopsy specimens, but he did a service in drawing attention to a condition which does not seem to have been mentioned since it was described in detail by Hare in 1838. Unfortunately Hare made no reference in his necropsy report to the condition of the lungs, and he was evidently of the opinion that his tumour arose in the neighbourhood of the brachial plexus.

It is clear that any lesion of the parietal pleura at the root of the neck which involves the brachial plexus and the sympathetic chain may produce the characteristic neurological disturbance—apical tuberculosis involving the pleura (Fried, 1934) has been responsible—and should the lesion be a neoplasm it may well bring about destruction of the adjacent bony structures. It is therefore not surprising to find reports of cases where such tumours as the following have been responsible: carcinoma of thymus (Browder and DeVeer, 1935), intrathoracic sympathoblastoma (Frost and Wolpaw, 1936), and metastasis from gastric carcinoma (Tobias, 1932).

Under the title of "sterno-clavicular branchioma" Fried (1935b) described two cases of men, aged 54 and

46, in whom there were tumours in the root of the neck on the left side and no evidence at necropsy of involvement of any other part of the body. These were both squamous-cell cancers, and did not appear to arise in the lung, the dome of the lung being adherent in one case and the pleura separating the tumour from the lung in the other. Graef and Steinberg (1936) subscribe to Pancoast's theory of the origin of such tumours from a branchial cleft, and describe the case of a man of 47 who had a tumour on the right side attached to a yellowish plaque on the pleura which did not extend into the parenchyma of the lung, although on histological examination the carcinoma cells, of mixed squamous and alveolar types, were seen invading the lung septa. Kelman and Schlezinger (1937), in describing another case of an obscure squamous-cell tumour, discard the hypothesis of its bronchiogenic origin, since fifth and sixth branchial clefts have never been definitely proved to exist in the mammalian embryo; they do not describe the appearance of the lung at necropsy, but remark that it was definitely excluded as a possible site of origin.

A Survey of the Literature

In the literature we found reports of nineteen cases coming to necropsy (Browder and De Veer, 1935; Clarke, 1934; Connolly, 1935; Davidsohn and Feldman, 1937; Fried, 1934, 1935a; Jacob, 1934; Jacob and Baker, 1937; Ryce, 1938; Stein, 1937; Steiner and Francis, 1934; Tobias, 1932) in which the tumours were demonstrably bronchiogenic carcinomata arising at the apex of the lung, extending direct into the ribs and vertebrae, and involving the brachial plexus and sympathetic chain. A further eight cases have been diagnosed clinically, with or without a histological examination of a biopsy specimen (Jacob, 1934; Stein, 1937; Steiner and Francis, 1934; Tobias, 1932). It is interesting to note that of the cases where the relevant data were recorded all were males, ten were on the left side and thirteen on the right, and the histological types were as follows: squamous twelve; adenocarcinoma five; undifferentiated or oat-cell two; unrecorded in the remainder.

We have found references to five further cases of bronchiogenic carcinoma of the apex of the lung in which adjacent ribs were involved, but the tumour did not happen to involve the nerves in such a manner as to produce the full syndrome of motor, sensory, and sympathetic disturbances (Fried, 1935a; Mareil and Crawford, 1936; Pancoast, 1932; Stein, 1937). All five of these were males—three of them on the left side and two on the right. Histologically one was an anaplastic round-cell type of carcinoma, two were squamous, and one an adenocarcinoma; in the fifth there was no histological report. It is just possible that one of the cases in this group described by Fried, and one of those in the last paragraph reported by the same author, may be an oat-cell type, since Fried (1935a) states that he considers this type of tumour to be squamous and apparently does not differentiate between them.

We wish now to report four cases of apical bronchiogenic carcinoma in which there was the full clinical syndrome described by Pancoast and three in which it was absent.

Case I

This patient was a man aged 46, by occupation a railway checker. In March, 1936, he had pain in the right shoulder and down the inner side of the arm, at first only at night, but later becoming a constant dull ache. Acute exacerbations radiated down the arm, chiefly on the inner aspect to the little and ring fingers. In October, 1936, he noticed weakness and wasting of

the right hand; this rapidly progressed and involved the fore and upper arm. Three weeks later he developed weakness of the legs, and was admitted to Bootle General Hospital on November 4. No cough, expectoration, or haemoptysis.

Examination.—Pupils unequal, right being myopic. Both reacted to light and accommodation. Slight right-sided ptosis and enophthalmos. The left pupil was large and the left half of the face was sweating profusely. Fundi and cranial nerves normal. Right arm flaccid, and wasting very marked in all muscles of arm and small muscles of hand. Typical right "claw-hand." Analgesia of inner aspect of right forearm, otherwise sensation in the arms was normal. The abdominal reflexes and knee- and ankle-jerks were absent. Both plantar responses were extensor. Sensation in the lower limbs and trunk was normal. Retention of urine. Chest: impaired percussion note over right apex posteriorly, otherwise no abnormal physical signs. Heart and abdomen: nothing abnormal. Urine: trace of albumin. Wassermann negative. Cerebro-spinal fluid: pressure 80 mm.; fluid clear and colourless; the pressure did not rise on compression of jugular veins, but a rapid rise was seen with abdominal pressure. The specimen tube was broken in transit to the laboratory.

X-ray Report.—There is loss of translucency in the extreme right apex due to a small shadow with a rounded base which appears to be eroding the lateral surfaces of the first and second dorsal vertebrae and is causing erosion of the posterior aspect of the second and third ribs.

The patient died on November 16.

Necropsy.—A hard circular tumour about 5 cm. in diameter and 1.5 cm. thick is present at the thoracic inlet on the right side, overlying and eroding the first, second, and third ribs near their spinal articulations. The apex of the lung is adherent to the mass. At its superior aspect the tumour extends into the neck, invading the brachial plexus and eroding the bodies of the sixth and seventh cervical and first and second dorsal vertebrae. It enters the spinal canal through the intervertebral foramina, and is found in this situation to be a soft mass surrounding the eighth cervical and first dorsal segments of the spinal cord, but it is not adherent to the dura, and the spinal cord is removed with its coverings intact to the naked eye. On section of the right lung it is seen that the tumour is within the lung parenchyma at the apex, and the line of the pleura cannot be recognized; it is therefore impossible to say just how far beneath the pleura the tumour extends. The region of attachment of the lung apex to the chest wall is well defined, and the tumour has extended in nodular masses over the parietal pleura beyond this attachment for a distance of 5 or 6 cm. The tumour has also spread medially alongside the trachea. No metastases or other pathological changes are present in the lungs or elsewhere.

Histological Report.—Carcinoma simplex with a considerable fibrous tissue reaction; parts of the tumour are of a scirrhous type.

Case II

A tram driver aged 48 was admitted to Liverpool Royal Infirmary on April 21, 1938, complaining of severe pain along the ulnar border of the right forearm and weakness of the right hand of six months' duration. He had noticed a swelling above the right clavicle for two months.

Examination.—Evident gross generalized wasting and marked pallor of skin and mucous membranes. Hard fixed tumour, size of orange, in right side of neck extending behind clavicle. Nothing abnormal found in lungs, heart, or abdomen. No enlargement of thyroid or lymphatic glands. Right pupil myopic; ptosis of right eyelid. Wasting of all muscles of right forearm and "claw-hand." Anaesthesia of ulnar nerve distribution. Wassermann negative.

X-ray Report.—There is a rounded opacity of the extreme right apex, the lower border of which is extending down to the fourth rib posteriorly. There is almost complete destruction of the first rib, and early destruction of the second rib, with a pathological fracture about an inch from the angle. The appearances are those of an apical lung tumour.

Operation April 22: chordotomy for relief of pain. Patient died on April 26.

Necropsy (twenty hours after death).—Emaciated, with a large fixed mass above the right clavicle. Wasting of right thenar and hypothenar eminences. The nasal sinuses, mouth, and pharynx are healthy. Both pleural cavities contain a little turbid fluid. There is a muco-purulent bronchitis and a bilateral basal pneumonia. A large mass of growth, involving and apparently arising from the extreme apex of the upper lobe of the right lung, has eroded the first and second ribs posteriorly and laterally. The greater part of the mass, which is 9 cm. in diameter, is situated above the clavicle, covered by the sterno-mastoid muscle and the cervical fascia. The brachial plexus is seen entering the mass from above, and reappears superficial to it at the level of the clavicle. It is not possible to find the sympathetic chain in the tumour. The right transverse processes of the lower two cervical vertebrae are eroded by the growth. The clavicle and scapula are not invaded. There is no glandular enlargement on either side of

extensors of the right wrist and fingers. Complete loss of power of the flexors of the wrist and all small muscles of the right hand and some loss of power in flexion of the fingers. The brachioradialis is unaffected, and the biceps and brachialis anticus are relatively strong. Deltoid and scapular muscles are normal, but there is winging of the right scapula. Impaired percussion note and deficient air entry right apex. Heart normal. Liver, spleen, and kidneys not palpable. Wassermann negative. No tubercle bacilli found in sputum.

X-ray Report.—There is an opacity in the extreme right apex which has a rounded lower margin extending towards the hilum of the lung. The shadow of the soft swelling extends up into the supraclavicular triangle, and there is early erosion of the third rib posteriorly. The appearances are those of apical bronchial carcinoma (Fig. 2).

Operation (March 16, 1935).—Portion of first, second, and third ribs excised posteriorly. The tumour was found to be attached to and arising from the apex of the lung. The whole of the tumour, together with a portion of the apex of the lung, was removed.

Pathological Report.—The tumour is a bronchial carcinoma showing the not unusual admixture of oat-cell structure, im-

FIG. 1.—Case II. The large apical tumour is firmly attached to the ribs and soft tissues at the root of the neck. A metastasis is present in the opposite lung.

FIG. 2.—Case III. Opacity in the right apex due to apical bronchial carcinoma

the neck or in the axilla. The tumour mass, on section, presents a yellowish-white appearance with some pinkish areas (Fig. 1). There are a few small cavities in the portion of the lung involved by the tumour, and these appear to be emphysematous bullae. There is a spherical blood-borne metastasis, 2.5 cm. in diameter, in the middle of the left lung. The paratracheal lymph nodes alongside the tumour contain tumour, but no metastases are present in any other organs.

Histologically the main tumour mass, which is very necrotic, is a carcinoma simplex. The pulmonary metastasis is better preserved and is in parts a definitely squamous-cell carcinoma.

Case III

A man aged 59, a forwarding clerk, was admitted to Liverpool Royal Infirmary on February 25, 1935. For six weeks he had had pain in the right shoulder, extending down into the hand, with "pins and needles" in the fingers. He had noticed drooping of the right eyelid for the last three months at least.

Examination.—There is a hard fixed mass in the right supraclavicular fossa, and the subclavian artery is more superficial than on the left side. No enlargement of thyroid or lymphatic glands. Definite ptosis of the right eyelid and a contracted right pupil. Complete loss of power of the triceps and

perfect papillary process formations, and incomplete alveolar arrangement.

The patient died on March 19, 1935. No post-mortem examination.

Case IV

A butcher aged 49 was admitted to Liverpool Royal Infirmary on July 25, 1932. Two months previously, after lifting a quarter of beef, he noticed stiffness of the right shoulder and found he had a lump above the right clavicle. During the following week he suffered from pain in right shoulder, right upper arm, and region of right breast. There was no history of cough, expectoration, or dyspnoea. He had lost about 1½ stone in weight in two months.

Examination.—Pallor of skin and mucous membranes and evident generalized wasting. Right palpebral fissure narrowed and right pupil contracted. Ptosis of right eyelid and right enophthalmos. No localized wasting. Tumour under right sterno-mastoid, about size of a walnut, extending behind clavicle. Dullness to percussion over right apex and diminished movement of apex with increased vocal fremitus and resonance and bronchial breathing. Two small glands in right axilla. Nothing abnormal found in heart or abdomen. Wassermann negative. No tubercle bacilli found in sputum.

August 4, 1932: Radium needles inserted into supraclavicular tumour—1,680 mg.-hours.

the liver, suprarenals, and nearly all the bones. The proptosis is due to a tumour in the orbital plate and zygoma. *Histologically* it is a well-differentiated columnar-cell carcinoma with large alveoli full of mucinous secretion.

Discussion

Apart from the interest these tumours have aroused among pathologists and radiologists, they are of great importance clinically, because in most cases no symptoms of pulmonary disease are present. Of the seven cases recorded above only one (Case V) complained of cough and expectoration, and in this the tumour was situated in the apex of the left lower lobe, and, moreover, there were complications—pleural effusion, emphysema, bronchiectasis, and terminal pneumonia. Again, there is a striking paucity of physical signs in the chest in most instances, and this is no doubt explicable by the position of the tumour and the absence of bronchial obstruction and complications commonly found in lung tumours that are not situated peripherally.

When there are symptoms and signs of involvement of the brachial plexus and cervical sympathetic chain one should consider the possibility of an apical lung tumour. In Cases I to IV the patients consulted their doctors because of pain in one or other upper limb, and they all had signs of brachial plexus and cervical sympathetic paralysis. The sequence of events in Case I is of particular interest, starting with neuritis of the right arm, followed some months later by wasting of the limb and claw-hand, and terminating with a compression paraplegia due to invasion of the spinal canal by the tumour mass via the intervertebral foramina.

The most remarkable feature of the radiological findings in these cases of peripheral bronchial carcinoma is the comparative smallness of the lesion compared with the severity of the symptoms. They are recognizable as rounded opacities at the periphery of the lung fields, with a convexity towards the hilum. In lateral and oblique views they are in direct contact with the chest wall, and in most cases, to a greater or lesser degree, they involve and cause destruction of the adjacent overlying ribs; this destruction is most marked when they are situated at the apex of the lung, and may so far progress as actually to involve and erode the lateral surface of the spine, a condition present in the late stages of Cases I and IV. These are the only points which characterize such lesions radiologically. They do not interfere with the chest and lung expansion except secondarily, nor do they show any characteristic defect with lipiodol beyond failure of that substance to enter the opaque area, and some associated compression of the surrounding lung field.

The observation that our four cases of carcinoma of the apex of the upper lobe and all the twenty-six recorded in the literature occurred in males is of no significance, since carcinoma arising in any part of the lung is very much more common in males than in females. Only two of the last twenty-eight cases of bronchogenic carcinoma encountered at necropsy at the Liverpool Royal Infirmary have been those of females.

The average age of the previously reported cases with the full Pancoast syndrome is 47, with extremes of 31 and 62. Our four cases were aged 46, 48, 49, and 59. The average age of the last twenty-eight cases of hilar bronchogenic carcinoma we have seen at necropsy was 50, with extremes of 31 and 75. There is thus no difference in the age incidence of apical and hilar cancer.

Little indication has been observed that one lung is more often affected with apical carcinoma than the other.

It is true that our first four cases, in which the upper lobe was affected, were right-sided, but of twenty-eight in the literature fifteen were right and thirteen left: the difference is not statistically significant.

There are no histological features of the apical carcinomata to differentiate them from those arising in bronchi near the hilum of the lung. Geschickter and Denison (1934) make a surprisingly definite statement in this connexion. They analysed sixty cases of bronchogenic carcinoma and divided them rigidly into two classes: those arising at the hilum, which are squamous, basal-cell, or oat-cell in type; and those arising in the periphery of the lung, which are "adeno-columnar, adeno-mucoid, or adeno-cubical." Our experience has been very different. In the last twenty cases of hilar carcinoma coming to necropsy nine were oat-cell, six squamous, four mixed oat-cell and squamous, and one columnar-cell; and of six of the peripheral carcinomata that we now report one was oat-cell, two squamous, one spheroidal-cell, one a columnar-cell adenocarcinoma, and one a mixed oat-cell and columnar-cell type. Samson (1935) reported ten cases of bronchogenic adenocarcinoma, of which only one was peripheral, the remainder arising at the hilum; and Tuttle and Womack (1934) remark that most of the well-differentiated tumours in their series were at the hilum. There is therefore a striking lack of agreement.

We have included Cases V, VI, and VII in this series because they were examples of peripheral tumours which did not happen to be at the exact apex of the upper lobe. In Case V the tumour was at the apex of the left lower lobe and had directly invaded the seventh rib and the corresponding thoracic vertebra. Old adhesions were present in the pleural cavity. The tumour behaved in exactly the same manner as the apical tumours, but failed to produce the same symptoms because of anatomical differences. In Case VI the tumour was sub-apical, there were no pleural adhesions in that region, and the growth had not invaded the chest wall; the presence of tumour in the ribs was a result of blood-borne metastasis. In Case VII also the tumour was subapical, there were dense pleural adhesions, and the growth had infiltrated the parietal pleura without, however, grossly invading the adjacent ribs. We should like to suggest that the presence of old organized pleural adhesions in the region where a peripheral carcinoma happens to develop may well favour direct invasion of the chest wall by the tumour; and since adhesions at the apex are more common than elsewhere it is not surprising that apical carcinomata so constantly behave in this manner.

In conclusion, we claim to have shown that the peculiar clinical syndrome associated with tumours at the apex of the lung can be fully explained on anatomical grounds, and there is no reason for considering such tumours to be different in other respects from bronchogenic carcinomata arising elsewhere in the lung. It is well to bear in mind, however, the possibility of other types of tumour, primary or secondary, at the root of the neck producing a similar syndrome.

Summary

The previously reported cases of tumours at the apex of the lung are discussed.

Seven new-cases of apical or subapical bronchogenic carcinomata are presented.

The clinical, radiological, and pathological features are discussed.

We acknowledge with thanks the kindness of the following gentlemen who have allowed us access to their case notes or

reports: Professor R. E. Kelly, Dr. H. Wallace Jones, Mr. H. C. W. Nuttall, Mr. R. Watson Jones, Dr. A. J. McCall, Dr. J. P. Steel, and Dr. MacWilliam.

AN OUTBREAK OF SONNE DYSENTERY

BY

Colonel C. J. TRIMBLE, C.B., C.M.G., D.P.H.

Medical Officer of Health, Preston Rural District

AND

W. C. V. BROTHWOOD, M.A., M.D., D.P.H.

Chief Assistant County Medical Officer of Health,
Lancashire County Council

On January 31, 1938, the bailiff of a farm in the Preston rural district gave information that some of the consumers of the milk produced there had been troubled with diarrhoea. The farm was visited forthwith and the following facts were elicited:

Particulars Concerning the Outbreak

1. The outbreak had started on January 26, and was characterized by diarrhoea and slight abdominal pains. The stools were slimy, but no blood was visible.
2. The cases were few, were limited to the consumers of the milk produced at the farm, and not all the consumers were affected. Among those affected were the four farm employees concerned with the production and delivery of the milk.
3. The quantity of milk produced was eight gallons daily. Four gallons of this were distributed. The remaining four gallons were mixed with milk from other farms and made into cheese.
4. No person at the farm had previously suffered from a similar illness.
5. The water supply to the farm was from two sources: (a) A shallow well: this water was used for washing the milk utensils. (b) A spring: this water was used for drinking purposes.
6. There had been no addition to the cattle for more than a year.

It was clear that the outbreak was milk-borne, and after consideration of the main features it was thought to be probably due to the Sonne dysentery organism. The following steps were accordingly taken:

(a) Distribution of the milk was prohibited for a period of two weeks in order that investigations could be made. Use of the milk on the farm was not prohibited providing it was boiled before use. No action was taken with regard to the cheese which had been made. The proportion of contaminated milk used in its manufacture was very small, and, further, it was known that conditions during "ripening" are so unfavourable that pathogenic organisms of the type under consideration do not survive.

(b) A list of consumers was obtained from the bailiff. (The list was subsequently shown to be incomplete, and this fact accounts for the delay in taking specimens in some cases.) Four of the households supplied with milk lived in the adjoining Garstang rural district. By arrangement with the medical officer of health of that district they were investigated by officers of the Preston rural district.

(c) Each household taking the milk was visited. Inquiries were made, specimens of faeces were taken where it was considered necessary, and instructions were given as to the disinfection of the hands, soiled clothing, and faeces of affected members.

(d) Samples of water from the well and spring were taken for bacteriological and chemical examination.

(e) All doctors practising within the area were notified of the occurrence of the outbreak.

The milk was supplied to twenty-four households, but only twelve were affected by the outbreak. Eighty-six persons were at risk, but only twenty-one became ill.

The graph shows the daily distribution of the cases, five occurring on the first day.

It is interesting to speculate as to the number of cases that were "primary" and the number "secondary"—that is, the number which resulted from the consumption of milk that was in a contaminated state when received, and the number which were infected by members of their own households. It must be accepted that the cases occurring on January 26 and 27 were "primary" cases, and it is clear that those occurring on February 4 and 6 were "secondary," because the milk supply had been stopped on February 1. The position with regard to the cases which occurred from January 28 to February 1 inclusive is not clear. It is possible that all these were primary, and due to a common continuing source of infection. On the other hand, in all cases except one there was in the household an infected member of at least forty-eight hours' standing, and in the exceptional case there was abundant opportunity for it to be infected secondarily. The possibility of "secondary" infection cannot therefore be dismissed. The advent of secondary cases indicates that the instructions given to members of affected households were not efficiently carried out.

Graph of the outbreak, showing the daily distribution of cases.

The Water Supply

Samples of water were taken from both the shallow well and the spring, and were submitted to bacteriological and chemical examination. The bacteriological examination gave the following results:

| | Shallow Well (Washing Water) | Spring (Drinking Water) |
|---|------------------------------------|-------------------------------|
| Bacterial colonies per c.c.m.: | | |
| Agar 37° C., 48 hours | 450 | 60 |
| Presumptive <i>B. coli</i> : | | |
| Calculated number of organisms of <i>coll.-aerogenes</i> group per | | |
| 100 c.c.m. | 1,600 | 70 |
| <i>B. dysenteriae</i> Sonne could not be isolated. | | |

The figures show that both samples were markedly polluted, and that they were unfit for domestic use. The chemical examination also showed that the water was unfit for use. The results are expressed in parts per 100,000.

| | Shallow Well (Washing Water) | Spring (Drinking Water) |
|---|---------------------------------|----------------------------|
| Total solids in solution | 22.8 | 48.8 |
| Oxygen absorbed from permanganate in 15 minutes | 0.144 | 0.028 |
| Oxygen absorbed from permanganate in 3 hours | 0.291 | 0.058 |
| Ammonia | 0.015 | 0.004 |
| Albuminoid ammonia | 0.038 | 0.0165 |
| Nitrogen as nitrates | 0.18 | 0.008 |
| Nitrogen as nitrites | 0.0022 | Nil |
| Combined chlorine | 2.3 | 3.2 |

As soon as the significance of the results of the examination of the water was communicated to the farmer he ceased to use it. He is now using for all purposes wholesome water carried from another farm, and he is considering the question of having the public water supply laid on.

Results of Examinations of Faeces

Bacteriological examinations, the results of which are given in the accompanying table, confirmed the suspicion that the outbreak was due to the Sonne dysentery organism. Several features are worthy of notice. The general tendency in this outbreak was for the organism to be present in the faeces for seven or eight days after

the attack, and to be absent after fourteen days. Exceptional behaviour, however, was shown by one or two cases. Thus Case 14, which began on January 30, was still excreting the organism on March 7, and Case 21,

starting on February 6, was also excreting the organism on March 7. Case 15 (a milkster) was exceptional in that negative results on February 4, 9, 16, and 21 were followed by a positive result on February 28, and this by four negative results.

Release of the Milk

On February 17 the question of releasing the milk was discussed, and it was decided to permit the distribution of the milk subject to certain safeguards:

(a) The continued use of the wholesome water for the washing of milk utensils.

(b) The suspension from duty for an indefinite period of the boy who delivered the milk: he was still excreting organisms on February 16 (Case, 6).

(c) Scrupulous attention to personal cleanliness by the bailiff and his two milkers.

(d) Further examinations of the faeces of the bailiff and the two milkers at weekly intervals. The bailiff (Case 13) and Case 15 had been consistently negative. With regard to Case 17, two negatives had succeeded the positive of February 4.

(e) The households taking the milk to be kept under observation.

It is particularly fortunate that (c) and (d) were insisted upon, because on February 28 one of the milkers (Case 15) was found to be excreting the Sonne organism. He was therefore prohibited from handling milk. Following negatives on March 7 and 21 he was allowed to resume work.

The Origin of the Outbreak

Though it seems clear that the outbreak was milk-borne, it is not clear as to the manner in which the milk became contaminated. On the one hand, it is possible that the polluted water which was used for washing the milk utensils was at fault. On the other hand, the milk might have been contaminated by one of the farm servants who handled it. There was, however, no history of any previous attack, and all of them were affected in this outbreak. The boy who delivered the milk can be excluded because he had not been connected in any way with the milk supply of three of the infected households.

Summary

An outbreak of Sonne dysentery due to contaminated milk has been described. About a quarter only of the persons exposed to infection suffered.

It was not found possible to determine the source of the contamination.

Administrative action was followed by a prompt cessation of the outbreak, except for two "secondary" cases.

The outbreak demonstrates the importance of repeated examination of the faeces of those infected if secondary cases are not to occur through a person's ignorance of the fact that he is still excreting the organism long after he appears to have recovered.

It also shows that it is particularly important during an outbreak of this type that repeated examinations should be made in the case of persons actually handling milk, and that they should be scrupulous in their personal cleanliness.

Our thanks are due to Dr. J. H. Cooke of the Preston Royal Infirmary, and Mr. J. R. Stubbs, the county analyst, for carrying out the bacteriological and water examinations.

RHEUMATIC HEADACHE

87

JAMES CYRIAN, M.D.

Little recognition has been given in recent years to the once well-known fact that headache can be caused by rheumatic infiltration of the muscles of the neck and scalp.

Historical Note

A rather hasty search in the old literature reveals that rheumatic headache was probably first described by Schönaich in 1615. His paper refers to headaches brought on by cold, arising in the pericranium and associated with tenderness there, and responsible for pain in the eyes and eyelids. Morgan (1769) remarked that headache might be rheumatic, and was then due to spasm of the cranial musculature, with resultant ischaemia. Weatherhead (1835) stated that rheumatic headaches took origin from the aponeurosis of the temporal and occipito-frontalis muscles, and drew attention to a variety in which pain was set up in an eye otherwise normal. Wright (1856) pointed out that the patient's sensations were not to be trusted, since tenderness was not restricted to the painful areas; that the pain might shift from the back of the head to the forehead, face, teeth, neck, and shoulder; that such headaches were apt to complicate attacks of acute rheumatism; and that they might be relieved by a mustard plaster on the neck. Norström (1902) described headaches due to inflammatory deposits in the neck and puffiness of the scalp, and drew the analogy of gluteal rheumatism giving rise to sciatica. He strongly recommended massage. Peritz (1906) infiltrated tender areas in the upper end of the sterno-mastoid muscle with 2 in 100 saline—first, to elicit muscle pain, and, secondly, as a method of treatment, thereby relieving a patient of a temporal headache. Whereas in the treatment of recent injury it is almost certainly the procaine, I am doubtful whether in the treatment of chronic myositis it is not the bulk of the saline solution that is the therapeutic agent; hence Peritz appears to have practised the very methods of provoking muscle pain and of treating it that are now regarded as the latest innovation. Yawger (1909) drew attention to indurations in the scalp which he termed the commonest and least-known cause of headache; he too advised massage. White (1912) seems to have been the first to notice that a pain in the ear might be caused by a distant myositis. Maverick (1913) pointed out that rheumatic headache might last for years and, if massage failed to bring relief, favoured excision of the nodules or injecting chromic acid into them. Hartenberg (1914) found that pain from the nape of the neck was perceived in the occipital region, and from the temple in the forehead and eyes. Patrick (1918) drew attention to the surprising lack of response to aspirin, and advocated massage or, if it failed, scarification of the scalp with the thermocautery. Glasscheib (1927) suggested injecting the nodules with a novocain-glucose solution.

The effect of all this information is to deprive the views about to be expressed of most of their supposed originality; nevertheless restatement of these facts seems timely in view of the oblivion into which rheumatic headache has fallen during the last twenty years.

Theoretical Considerations

The fact that pain in certain parts of the head might originate from distant points had long been apparent to me

clinically as a result of the search for the spots massage of which relieved the patient's headache. However, not until the publication of Sir Thomas Lewis's (1938) way of producing muscular pain artificially was I able to co-ordinate these clinical impressions and put them on an experimental basis. The method of injecting hypertonic salt solution described by J. H. Kellgren (1938) turned out to be most helpful, and gave confirmation and precision to the rough clinical findings. Injections of 0.1 c.c.m. of a 4 per cent. solution of salt were made at various points into the occipital, the temporal and the upper parts of the posterior and lateral cervical muscles, and into the epicranial aponeurosis. There was always pain at the site of injection, with reference to a distant area unless the fluid was faultily placed—for example, on to the periosteum. Irritation of fibres of the posterior cervical muscles close to their occipital insertion, and of the occipitalis itself, gave rise to a pain running forwards like a band half encircling the head and reaching its maximum intensity in the temple and forehead over the eye. From punctures between one and two inches below the occiput the pain radiated up the back of the head to the vertex, from punctures below this point the pain did not go beyond the upper end of the cervical muscles. From punctures at the upper end of the sterno-mastoid muscle the pain was referred to the temporal region, and stimulating a small area over the lower central part of the parietal bone gave rise to pain felt in the pinna and, in one case, in the external auditory meatus. Injection into the temporal muscle caused a pain in the cheek and jaws. Injections into the epicranial aponeurosis set up pain referred to the eyes—behind the eyes, in the eyeball, in

Diagram showing the areas of origin of pains referred about the head and face.

the eyelids. Over the posterior part of the parietal bone appeared to lie a "silent area" whence pain was referred only a short way. In no case did the pain cross the mid-line. The accompanying diagram shows, albeit roughly, the main areas of origin of pains felt in the head. In every case the referred pain was felt right inside the head and bore no resemblance to what the patient might have supposed would be caused by so superficial a lesion.

I had believed that the aponeurosis joining the occipitalis and frontalis muscles was analogous to a tendon, and was therefore surprised to find that irritation of the aponeurosis set up the remote pain characteristic of muscle rather than one restricted to the much smaller ambit of reference from tendon. An explanation, however, was to hand in the fact that embryonically the occipito-frontalis is a continuous sheet of muscle, whose central portion later becomes fibrous; hence the aponeurosis may well retain some of the properties of muscle. Thus rheumatic headache can be brought into line with other well-known pains of undoubtedly muscular origin—for example, "sciatica," "brachial neuritis"—in all of which the quality of the pain is the same. Furthermore, I feel sure that the head-

ache that accompanies a sore throat is referred from the pharyngeal muscles, but I did not go so far as to try to inject them with saline.

Clinical Considerations

By consideration of the following points it is not difficult to distinguish rheumatic from other kinds of headache.

History.—The patient has often had previous attacks of rheumatism, and may even come correctly self-diagnosed. The headache has usually been preceded by influenza or a cold, or a streptococcal disease like scarlet fever, and there is often a complaint of a neck still, or recently, stiff.

Symptoms.—The position of the continuous indefinable ache is difficult to ascertain, since the patient feels it to be right inside the skull. If pain is referred to the region of the eye there is no interference with vision, or optical hallucinations, or nausea, as in migraine. As a rule the headache is present on waking, and bending down with the neck rigid does not aggravate the pain, contrary to experience in other kinds of headache. If the patient sits still bent over a book for some time a headache comes on, and the neck feels stiff and may give out cracks on movement. Moving the neck may hurt the head, and the patient may be free from pain with the head supported; or the scalp in the occipital region may be so tender that the patient cannot bear the pressure of a pillow there at night. The pain is not sharp or momentary as in "neuralgia." Large doses of aspirin hardly abate the headache at all.

Signs.—Rheumatic headaches may conveniently be separated into two categories: pain in the head referred from the cervical muscles, and pain in the head due to changes in the scalp. Obviously the signs will differ according to which kind of headache is present, and the two not seldom occur together. Pain elsewhere may or may not be referred, but in rheumatism pain in the forehead does not seem ever to originate there.

Pain Referred from the Cervical Muscles.—There is a diminished range of movement in the neck, with pain on attempted movement which radiates to where the headache is felt. There is tenderness of the posterior or lateral cervical muscles in their upper part, where the grating and stringiness typical of long-standing rheumatism are often palpable. If the condition is at all acute the referred pain can be elicited or aggravated by rubbing the tender spot in the muscle firmly. The diagram above will give a rough indication of where to look for muscular tenderness, from a consideration of the place to which pain is referred.

Pain due to Changes in the Scalp.—In really bad cases there may be pitting oedema with fibrous nodules in the scalp over the occipital and parietal bones; such patients have had many years of constant severe headache. Usually, however, there are some slightly thickened grating areas no bigger than a sixpence and barely perceptible to the examining finger. They are tender, and as a rule are placed symmetrically, or nearly so, on the two sides of the head. Favourite spots are over the central part of the occiput about an inch from the mid-line and about the centre of the parietal bone. Firm pressure on these spots gives rise to both local and referred pain, though the patient had nearly always been aware only of the latter.

From the negative point of view the absence of neurological signs is confirmative.

Treatment

In fibrositis of the scalp treatment is not difficult. Massage must be given daily until the symptoms have gone. In advanced cases the thickenings in the scalp do not disappear; they merely cease to hurt. Provided the correct spots are massaged firmly and persistently there should be next to no failures. The diffuse occipital fibrositis that so often follows influenza may yield immediately to one treatment and not return. When there is long-standing induration of the scalp, massage may have to be continued for some months. I have not tried the effect of infiltration of the scalp areas with procaine, partly because in my experience this treatment, admirable for muscle, is useless for lesions in fibrous tissue, and partly for fear of injecting the procaine solution into a vein with intracranial connexions.

In rheumatism of the cervical muscles these must receive deep friction across their fibres, followed by passive stretching, and the increased range must then be maintained by active exercises. In mobilizing the neck day by day, particular attention should be given to lateral bending, which is often more limited than flexion and extension or rotation. If tender spots persist in the muscles after adequate massage their infiltration with 1 in 200 watery solution of procaine is often very helpful. Fibrous tissue in a muscle can to some extent be softened by injections into it of a 1 in 50 solution of procaine in olive oil, and this is more worthy of trial than the watery solution in cases where the muscle feels rough and stringy.

Commentary

If the points of origin of rheumatic headache are looked for according to the above diagram many hitherto unexplained headaches will be found to fit into the two categories described. Obviously many patients with headache and a pain in the eye or ear who may be referred to the appropriate special department, there to be labelled "neuralgia" on the discovery of a normal visual or auditory apparatus, and some of those in whom a post-influenzal frontal sinusitis is at first suspected, may be afforded relief if their symptoms are understood.

Osteopaths have claimed to cure headache. This is not impossible, since massage of the head and neck followed by mobilization, however foolish the theory on which it is based may be, is obviously sometimes excellent treatment.

It is probably fair to say that a headache that goes on for years without altering appreciably or making the patient ill is rheumatic. Apart from these uncommon cases, those who suffer from less persistent headaches can be given great relief by the use of massage if only the existence of this sort of headache is kept in mind.

Clinical Memoranda

Reviews

Bilateral Rupture of Quadriceps Tendon

There appears to be no reference in the literature to the occurrence of bilateral rupture of the quadriceps tendon above the patella. The following case was treated in Charing Cross Hospital by Mr. R. A. Fitzsimons, by whose permission these notes are submitted.

CASE REPORT

A Covent Garden porter aged 66 fell down four stairs late on Christmas Eve. His right knee was so injured that he was unable to straighten it. After an interval of rest he pulled himself up and, putting all his weight on the left leg, managed to descend the remaining stairs and was hopping across a landing when his left leg gave out in a similar manner. He estimates the time interval as about half an hour. He pulled himself up by a window-sill, and attracted the attention of passers-by in the street, who came to his help.

He was admitted to Charing Cross Hospital, and was found to have a bilateral rupture of the quadriceps above the patella, with the characteristic hollows over the lower end of the femur, an effusion into the knee-joint, and complete loss of the power of extension. At operation under tourniquet five days later it was found that both tendons were completely avulsed from the upper borders of the patellae, with tearing of the lateral expansion. The knee-joints contained blood. The patella was drilled transversely, and kangaroo tendon was used to approximate the bulk of the ruptured tendon to it. The lateral expansion and aponeurosis were sutured with catgut. The patient made a good recovery, being discharged a month after operation. Flexion to 90° degrees was regained in three months.

COMMENTARY

Rupture of the quadriceps tendon is by no means uncommon, and is caused by the violence of a sudden muscle pull—that is, the same mechanism as that which brings about transverse fracture of the patella. The available figures give the comparative frequency of the two lesions as four cases of ruptured tendon to 318 fractured patellae. Tendon rupture occurs typically in men past middle age, and it has been assumed that the tendon is weakened through fibrosis from old injury, syphilis, arteriosclerosis, or obesity. The rupture is usually complete, although a slender deep process may remain intact. The separation may be from two to six inches, varying with the completeness of the tear and the length of time that has elapsed since the injury. The tendon is more frequently torn cleanly from the bone, but a fringe may be left attached to the patella.

The classical signs, occurring as they most frequently do in an elderly man, comprise evidence of haemarthrosis, a hollow above the knee-joint through which the lower end of the femur becomes palpable, and the complete loss of active extension at the joint. The accepted treatment is by suturing with fascia or kangaroo tendon, the patella being drilled transversely, unless enough tissue remains attached to the bone to hold the sutures. The tear in the lateral expansions must also be closed. The restoration of function is good, and is almost complete within five months.

CHRONIC ABDOMINAL DISEASES

Chronic Diseases of the Abdomen: A Diagnostic System. By C. Jennings Marshall, M.S., M.D., F.R.C.S. (Pp. 247; 131 figures. 25s. net.) London: Chapman and Hall, 1938.

This volume covers in an unconventional manner all the chronic diseases which occur in the middle portion of the human frame. The term "chronic abdomen" has been used so widely as to include every variety of intestinal trouble: the liver, the pancreas, the urinary system, and even the lower spine. A chapter on physical examination is followed by one on special investigations of the intestinal tract and the renal apparatus, which are treated in some detail. The next hundred pages deal with abdominal pain, first of all as vague and general, then as epigastric, and finally in other local regions. The remainder of the volume deals briefly with such special conditions as haematemesis, ascites, jaundice, and haematuria.

Throughout the book every subject is dealt with in the tabular manner which is now so popular with the student, and the letterpress is illuminated by variations of type which are certainly unusual and perhaps a little futuristic. Descriptions of symptoms are very much to the point, and suggest that the author's reference to Rabelais is more than accidental, for the method of presentation would certainly have met with his approval. The volume is admirably illustrated by photographs and radiographs and by sketches which give a student just the information he requires. It is a book from which the student can gain a great deal of information in the very brief time that he has at his disposal for reading.

PNEUMONIA

The Pneumonias. By Hobart A. Reimann, M.A. With a foreword by Rufus Cole. (Pp. 381; 111 illustrations, 17 tables, and frontispiece. 25s. net.) London and Philadelphia: W. B. Saunders Company, 1938.

The changing outlook on the subject of pneumonia is well exemplified by Dr. Reimann in his book entitled *The Pneumonias*. That change may be largely attributed to the typing of the causative organisms which, though initiated by Lister in South Africa in 1913, was systematically elaborated at the Rockefeller Institute under the direction of Dr. Rufus Cole, resulting in the recognition of the four groups as proposed by Dochez. Dr. Reimann was then a resident in the hospital of the Institute and devoted much attention to the subject—an attention which he has continued now that he holds a chair at Philadelphia. Of that prolonged study this book is the outcome. He has cast his net wide, for he includes many acute infections of the lung besides those due to any of the types (now extended to far more than four) of pneumonia, and does not exclude those due to infective granulomas which may run a chronic course.

The first part of the book is devoted to specific forms due to various cocci, bacilli, and filterable viruses, and also to fungi and moulds. The second part deals with pneumonia as a complication of systemic disease, while the remainder treats of a variety of pneumonic inflammations produced by mechanical causes, radiotherapy, etc. The whole therefore forms a comprehensive survey which is copiously illustrated by a valuable series of x-ray photographs. Perhaps the most important section is the study of pneumococcal pneumonia, as this includes so much of

THE PITUITARY GLAND

The appearance of a book of 724 pages published by the Association for Research in Nervous and Mental Diseases and entirely devoted to the pituitary gland¹ forcibly reminds us of the rapid advances in the study of that organ. For the whole subject is only just over forty years old. True in 1886 Marie described acromegaly, but it was not till the following year that Minkowski suggested that it was due to over-functioning of the pituitary, though on grounds which now appear rather inadequate. In 1895 Schäfer and Oliver prepared an active extract from the gland, thus repeating their success in obtaining an active suprarenal extract the previous year. Soon afterwards Howell showed that it was only the posterior lobe which yielded pituitrin. The year 1900 was marked by two steps forward, for Benda observed the excess of acidophilic cells in the anterior pituitary in acromegaly and Babinsky described a case of hypopituitarism. Generally speaking neither of these facts received the attention it deserved, but the seed fell on good ground in Sir Charles Sherrington's laboratory at Liverpool, where both Harvey Cushing and Fröhlich were working at the time. The next year Fröhlich returned to Vienna and described the hypopituitary syndrome which still goes by his name, and Cushing went back to the United States to initiate a combined surgical, pathological, and experimental attack on the problems that were just emerging. It will be generally agreed that no one man has done so much by his own work and his stimulating effect on others to elucidate and illuminate these problems as Harvey Cushing. And so it comes about that although he has not contributed an article to the monograph before us, his influence is writ large upon it all.

The investigations which started then have led to some valuable conceptions of general importance. Thus we have learned that the pituitary, like the adrenals, acts as a transformer of nervous stimuli into chemical secretions; its close association with the centres of emotional expression has served to link biochemistry with psychology; its

richness in tropic hormones has led to a conception of the integration of the endocrine system. In other words, if the pituitary is to be regarded as "the leader of the endocrine orchestra" we have come to see that the hypothalamus is its conductor. This is not to deny that the endocrine system has autonomous activities according to the daily biochemical needs of the body, but it has become clear that this system can be activated or inhibited by the hypothalamus through either the chemical mechanisms of the pituitary or the nervous mechanisms of the sympathetic. No doubt in the ordinary way the chemical secretions of the pituitary pass into the venous system, but it is also evident that some of its effects are due to their passage through the stalk of the gland into the cerebrospinal fluid. This appears to apply particularly to the oxytocic principle, but Raab has also shown that the influence of the pituitary secretion on fat metabolism is more potently exercised through the lateral ventricles of the brain than through the blood stream.

Through a study of the pituitary new light has been thrown on such important problems as normal and abnormal growth, infantilism, diabetes, Graves's disease, and the interaction of the sex hormones. Coincidentally with this increase of biochemical data there has been a sobering down of the speculations on the influence of the gland on the temperamental make-up of the individual. Nevertheless Rowe found that of sixty-eight children suffering from endocrine disturbances associated with disorders of behaviour, fifty-three showed pituitary dysfunction, indicating the importance of the connexion. All this and more also will be found fully discussed in the present monograph. From the wealth of material which it contains we will select a few outstanding examples. A. E. Severinghaus gives a particularly clear and well-illustrated account of the cytology of the pituitary, in which he adopts the now generally accepted view that the chromophobe cell is the parent of the acidophilic and basophilic ones. This explains the temporary nature of some cases resembling Fröhlich's syndrome; they are not due to a chromophobe adenoma but merely to a delay in the differentiation of the parent cells. The double origin of the pituitary has always been a subject of great interest to the embryologist, especially in its evolutionary aspect, and Dr. Fredrick Tilney discusses this very fully in a chapter entitled "The Glands of the Brain," drawing a contrast between the variability of the cerebral glands connected with the roof of the brain and the constancy of the floor glands. The variability he interprets as an adaptation to the needs of the individual species, while the constancy expresses certain dominant themes common to all vertebrates

¹ *The Pituitary Gland. An Investigation of the Most Recent Advances.* Editorial Board: Walter Timme, Angus M. Frantz, and Clarence C. Hare. Baltimore: Williams and Wilkins Co.; London: Baillière, Tindall and Cox. (45s.)

from beginning to end. The long-established structural constancy of the pituitary indicates its indispensable nature, just as its complex differentiation implies the possibility of widespread tropic influences. Dr. Walter Timme, whose views are always interesting, if sometimes rather challenging, contributes a critique of the pituitary theory of migraine, of which he is more in favour than are some other authorities. The questions of water balance and diabetes insipidus are fully discussed by various writers, and naturally Cushing's syndrome of pituitary basophilism comes in for considerable notice.

We have referred to the length of the book, and if one small criticism may be made we would hint that American writers are tending to a Teutonic discursiveness which might with advantage submit to the blue pencil. Nevertheless this is an admirable record of an abundant harvest reaped in a brief twosecure of years.

ECONOMIC STATUS AND HEALTH

In collaboration with Dr. A. Grant Fleming, Professor of Public Health and Dean of the Faculty of Medicine in McGill University, and with Mr. C. F. Blackler, a former social research assistant, Mr. Leonard C. Marsh, the director of social research in that university, has, under the auspices of his university and through the Oxford University Press, published a volume, entitled *Health and Unemployment*,¹ containing an account of some careful and interesting studies of the relationships of those conditions throughout the Dominion of Canada or in its various Provinces. The book—like the surveys the results of which it embodies—does more than attempt to answer the questions how far the unemployed are in need of medical care, or what are the medical and physical implications of being unemployed. It describes and discusses also the effect of the industrial and economic depression on the development of social welfare organization in Canada. The main study dealing specifically with health conditions is based upon the results of complete physical examination of 1,000 unemployed adults, compared with 1,000 employed men, and 270 unemployed youths, both classified according to their occupational or economic status. There were other somewhat similar studies relating to groups of socially assisted unemployed families, school children, and infants. The results are set out in no fewer than 115 charts or statistical tables. These

are clear and informative and of very varying interest and merit. Indeed, the value of these results as a whole cannot be placed very high, either because of the relatively small numbers of persons concerned, or because in almost every case they can be legitimately interpreted in divers ways and may even be held to lead to quite different or contradictory and opposite conclusions.

Mr. Leonard Marsh and his co-investigators naturally admit that the measurement and assessment of health conditions is not a simple matter. It becomes clear, too, that the problems considered are not those of unemployment *per se*, but rather those of economic status among the employed and unemployed alike, and even so that they have to be dealt with in relation to sex, age, and other relevant circumstances. Moreover, it is not easy in many cases to distinguish between cause and effect: is ill-health or mental disturbance or physical disability the cause of unemployment, or is it the other way round? The authors do not really attempt to elucidate these problems, though it is suggested (in a footnote) that the relationship of ill-health and unemployment is not one of cause and effect either way, but that both are the joint result of economic, social, and personal factors. This may be so, but it is perhaps a little surprising to read that the "evidence justifies the estimate that at least 20 or 30 per cent. of the unemployment problem is a health problem so far as remedial treatment is concerned." If this means that from one-quarter to one-third of the total unemployment could be got rid of by better medical attention to the unemployed the situation is less unhelpful than it might be.

For the medical profession the most important, valuable, and interesting part of the work is that entitled "The Provision of Medical Care." This section of some fifty pages describes in sufficient detail and with admirable clarity the medical provision made, or in the making, for the unemployed and the necessitous in Eastern Canada and in Western Canada respectively. It discusses also the relation of medical relief to systems of health insurance, and recent steps taken, including two provincial Acts on the statute books in Alberta and in British Columbia, towards the establishment of federal or provincial systems of health insurance in the Dominion. The conclusion is reached that such a federal scheme of insurance is definitely the most satisfactory solution, and that it should include provision for the destitute and the unemployed on lines similar to that for others who are unable to make the needed medical provision for themselves. The most extensive and satisfactory schemes of medical relief at present are those established in Ontario and in Montreal. The

¹ *Health and Unemployment. Some Studies of their Relationships.* By Leonard C. Marsh. In collaboration with A. Grant Fleming and C. F. Blackler. London: Oxford University Press. (10s. 6d.)

nature of these schemes, as well as that of others on a more restricted scale in other parts of Canada, is adequately set out, and should be studied with interest by those engaged in health-insurance or public assistance administration in this country. For this part of his book Mr. Leonard Marsh deserves special thanks.

EARLY DIAGNOSIS OF CANCER

The improved outlook in cancer is due in part to better technique in treatment, but in part also to better and earlier diagnosis. The importance of early diagnosis is indeed so overwhelming that much effort has been made and a good deal of money spent in trying to educate the public on this subject. How much effect such propaganda can have is uncertain, and both the spoken and the written word can cause unnecessary apprehension besides perhaps doing good. Periodic medical examination in middle and later life is undoubtedly desirable, but how frequent it should be and to what lengths it should go are other questions on which there is no general agreement. But whatever doubt there may be about the education of the public in this matter there is none about the imperative need for a fully educated medical profession. A patient attentive to the possible first signs of cancer can have his vigilance rewarded only by a doctor with the knowledge and diagnostic ability to interpret them. These qualities, and the acumen, also based on knowledge, which will descry in the trivial symptom a danger signal calling for further investigation, are capable of higher development in most of us. No one has ever pretended to estimate how often the blame for delayed diagnosis rests on the patient and how often on his doctor, but were such an analysis possible the medical profession would not be entirely exculpated. If it be granted that education of the profession is at least as much to be desired as that of the public, an important service has been rendered by the Canadian Medical Association in publishing a *Handbook on Cancer* intended for the general practitioner.¹ This book of 232 pages is simple and unencumbered by illustrations or masses of figures, but it has been written by experts and furnishes an admirable account of the pathology, symptomatology, diagnosis, and treatment of cancer in every part of the body. The information given is authoritative, up-to-date, and surprisingly full and detailed for chapters so brief and easily read; that on bone tumours, for example, clearly describes and distinguishes between the four types of primary growth in bone, and the very different course taken by each of them. In describing symptomatology, emphasis is laid on the first presenting symptom, and a graphic picture given of the features by which the disease should first be recognized or suspected. Methods of examination, both simple and special, are adequately described; there

is, for example, an excellent account of the use of inspection and palpation in detecting a carcinoma of the breast, while various endoscopic methods and procedures for securing a histological diagnosis are assigned their place and value. The rules given for treatment are precise and well informed, and the prognosis is stated in terms as exact as a few well-chosen figures can make them; when treatment by irradiation has been shown to be fruitless this is plainly stated. The possibility of prophylaxis is not forgotten, predisposing causes being mentioned where they are known to exist, and precancerous conditions described. The chapters on cancer of different organs follow accounts of the general principles of treatment and those underlying radiological treatment and an introductory chapter on the general pathology of the disease which furnishes an admirable summary of the present position of cancer research. Almost everyone has something to learn from a book such as this, and to many without special experience and training it can be a most valuable guide. Some of the funds available for promoting the study and improving the treatment of cancer could scarcely be better spent than in sending a copy of this book to every practitioner in the country. The *Canadian Medical Association Journal* in announcing its publication says that free copies have been presented to members of the C.M.A. as a contribution to the nation-wide campaign against cancer. Applications from other members of the profession should be addressed to the General Secretary, Canadian Medical Association, 184, College Street, Toronto.

OEESOPHAGITIS IN INFANCY

It is probable that anyone asked about the frequency of inflammation of the oesophagus in young infants would reply that it is a rarity and generally diagnosed only at necropsy. Diagnosis during life in an infant who cannot complain of pain or difficulty in swallowing is obviously not easy, but it should be simplified to some extent by a study of the recent paper by J. H. Ebbs.¹ Twenty-eight children have died with an acute oesophagitis at the Birmingham Children's Hospital during the past three years. Working back from the post-mortem findings, Ebbs sets out the clinical features of the disease. It appeared in twenty-two instances to be due to infection by the organism causing thrush—*Monilia albicans*; in these infants there was always a previous history of thrush of the mouth. The outstanding observation made by mothers or nurses in these cases of acute oesophagitis was that the infant cried during or immediately after the act of swallowing, or that it refused to feed. Many infants in this series would take the liquid into the mouth and then allow it to dribble. The chief complaint was vomiting; if swallowed the food was either immediately regurgitated or returned as a large forceful vomit during, immediately after, or within a short time of the feed. Dehydration became a serious factor in association with frequent vomiting, and toxæmia seemed to develop.

¹ *Handbook on Cancer for the Medical Profession*. The Authorship Committee Department of Cancer Control, Canadian Medical Association. Toronto, 1938.

¹ *Arch. Dis. Childh.*, 1938, 13, 211.

usually a few days after the onset of severe symptoms. The temperature was slightly raised in some instances, but was often subnormal; the pulse was always rapid and usually irregular; diarrhoea was never an outstanding sign. Periods of apparent recovery alternated with periods when the child appeared to be dying, and terminal bronchopneumonia occurred in nearly all cases. It is clear from this study that treatment must be prophylactic; in other words, ordinary thrush must receive adequate treatment. In the present cases borax and glycerin has been disappointing, but the application of an aqueous 1 per cent. solution of gentian-violet has been found most satisfactory. It is said that one application will clear the lesions in the mouth, and if an infant with thrush in the mouth refuses feeds, vomits soon after swallowing, and shows a deterioration of its general condition with a toxæmia out of all proportion to the signs present it should be suspected of thrush oesophagitis, and gentian-violet should be applied liberally to the mouth in the hope that it will reach the affected areas in the oesophagus. Ebbs concludes his interesting paper with the description of one such case successfully treated.

PLANT GROWTH HORMONES

The study of hormones is being energetically pursued in plant physiology and is even finding some applications in horticulture. Animal hormones have been described as peculiar in the respect that they are produced in one organ and carried by the blood stream to another, in which their effects are manifested. There is no circulatory system corresponding to the blood in the higher plants; nevertheless the action is somewhat similar. The plant growth hormone can be described as a substance which, being produced in one part of the organism, is transferred to another part and there influences a specific physiological process. In a recent lecture to the Pharmaceutical Society of Great Britain Mr. W. G. Templeman, who is engaged in research on plant physiology, described the nature and use of these hormones and of the synthetic growth-promoting substances, the preparation of which, as in medicine, has followed upon the discovery of the hormone. After the isolation from human urine of auxin *a* or auxentrionie acid, a substance of similar activity known as auxin *b* or auxinolonie acid was isolated from maize-germ oil. Neither of these substances has as yet been synthesized, but it has been ascertained that auxin *a* is present in the higher plants, and recent work suggests that another substance, the heteroauxin or β -indolacetic acid, of about half the activity of the former, which has been synthesized, is also present, though it is not yet known how widely it is distributed. Altogether some fifty compounds from synthetic and other sources are now known which have growth-promoting properties. The effect of plant hormones is to produce cell elongation and division, though it is still not known whether in division the hormones are the only chemical factors concerned. The application of synthetic growth substances to young

stems results in a large swelling of the tissue, very similar to the tumours produced by certain pathological organisms. Thus a gall may be produced on making a cut and smearing the wound with indolacetic acid. Another interesting effect is bud inhibition. It has been found that the young developing terminal bud produces a hormone which diffuses downwards and inhibits the growth of lateral buds, and if the terminal bud be replaced by auxin *a* or *b* the development of the lateral buds is still inhibited just as if the terminal bud were present. Various changes can be rung on the flowering cycle of plants. The flower hormone or florigen is regarded by a Russian worker as the sex hormone of the plant, and by its use blossoming has been accelerated and non-flowering plants have been made to flower. The increased growth of plant tissue upon the approach of the pollen tube is also thought to be due to excretion of some hormone substance from the tube. A ripe tomato fruit has been produced by the application of indole-propionic acid to the style of an unpollinated tomato flower. It has been discovered that by the treatment of the stem of a plant either by paste application or by injection of heteroauxin in lanolin, after intervals of varying lengths according to the species, there appear adventitious roots along the stem. Experiments have been carried out with cuttings standing in vessels filled with aqueous solutions of synthetic substances such as indolacetic acid or indolbutyric acid, and a number of them respond by developing roots although they may have remained unrooted for months. But even in plant physiology the path of hormone research is not smooth. Cuttings from some plants are very difficult if not impossible to root, whatever the application of synthetic substance, and, moreover, cuttings of the same variety taken from different plants sometimes behave differently in their response to growth-promoting hormone. The work is proceeding at Kew, where there is a plant hormone committee, and in various other laboratories, and may some day result in revolutions of major or minor extent in plant production. Miss Dorothy Brain¹ has suggested that the possibility that the raw materials of some animal hormones may be derived from plants may have to be taken into account in interpreting the symptoms of deficiency diseases.

PSYCHIATRIC PREPARATIONS FOR WAR EMERGENCY

Among all the speculations with regard to medical preparation for a national emergency, problems of psychiatry have been receiving much consideration from those whose special concern is with this branch of medicine. The fact that in a disciplined body of men there was so much neurotic breakdown in the great war—and there were over 70,000 such patients in 1918—is a clear indication that the disturbance of the stability of the untrained civilian population of our cities would be very considerable in case of air raids of the sort that are to be expected. The evidence from Spain as to incidence of neurotic breakdown under

¹ *Lancet*, 1937, 1, 1241.

somewhat comparable circumstances is conflicting, but it is clear that preparation must be made in all plans for dealing with this group of civilian casualties. In our advertisement columns there appears an announcement of a short course of lectures arranged by the Tavistock Clinic on "The Neuroses in War Time," which is designed to give some insight and elementary instruction to those who would have to grapple with such problems in emergency. Those doctors who are to be in charge of first-aid stations will certainly need some help with this aspect of their work, just as they will need special instruction in the most modern techniques in regard to fractures, burns, etc. Many others who realize the problems with which they may be faced, whether in hospital work or in general practice, will no doubt welcome such lectures, and if this experimental course proves as useful as is expected it should be capable of repetition, not merely in London but in other cities and towns throughout the country. Many of those who attend this course will no doubt, as a result of the lectures and the discussions that follow them, be in a position to carry on such instruction for their colleagues elsewhere. We note that all the lecturers in this first course have been chosen from among those who had experience in the last war, though it is questionable whether there are any precedents to serve as a guide in making medical plans for a possible future war.

THE USES OF TISSUE CULTURE

The annual report of the Strangeways Research Laboratory at Cambridge for 1937 records that no fewer than twenty-five investigators worked there during the year, and the brief outline given of the objects and results of their work illustrates the variety of purpose which the tissue-culture technique is now being made to serve. By the cultivation *in vitro* of large portions of embryo it has been possible to throw light on obscure questions in embryology. Thus the researches enumerated in this report include studies of the mode of formation of the mandible and of the sternum. A good deal of other work has been concerned with factors controlling growth; in this category are studies of the effect of pressure on cartilage formation, and of the relation between blood pressure and the thickness of the arterial wall. The conclusion on this point is that pressure alone does not explain variations in the thickness of the vessel wall in different parts of the embryonic arterial tree. An *in vitro* study of developing teeth is thought to have shown that the shape of the cusps is controlled by factors in the tooth germ itself, and is independent of mechanical conditions in the jaw. In grafting experiments with tissues derived from races of different size genetic rather than immediate factors have also been shown to be the more influential. On the more pathological side there have been studies of the causes of fibrillation in heart muscle, and several observations on infective processes *in vitro*. Many bacteria would doubtless destroy a tissue culture within a few hours, but it has been found possible in the past to

introduce such slowly growing bacteria as tubercle bacilli and to observe the mutual behaviour of these and the tissue cultivated. In the present experiments fungi were used, and two conclusions have been reached on the basis of experiments with *Monilia albicans*—namely, that its destructive effect on lung cultures *in vitro* corresponds to its degree of pathogenicity *in vivo*, and that it has not, as has been suggested, a specific action on ciliated epithelium, since cultures of this tissue will survive in the presence of the fungus for as long as fourteen days. The Strangeways Laboratory is now even better equipped than before for studying the effects of irradiation, and work has been done on the degree of susceptibility to x rays of different processes in cell metabolism. The factors controlling the effects of irradiation have been studied in tadpoles—one of many more primitive forms of life, ranging from the roots of beans to the eggs of flies, which have been tried for this purpose—and the results appear in several ways to confirm the long-held belief that metabolic activity, and in particular the imminence of mitosis, determine the susceptibility of the cell to irradiation. All the work described here has evidently a fascination in that it deals with living material which is yet under complete control; whether these *in vitro* conditions are such as always to justify conclusions applicable to the whole body has yet to be decided.

A NUTRITION PANEL

The formation of a Nutrition Panel consisting of prominent food experts and scientists in every branch of research and industry is announced by the Food Group of the Society of Chemical Industry. The Panel, with Dr. J. C. Drummond, professor of biochemistry at London University, as chairman, Mr. A. L. Bacharach as honorary secretary, and Dr. G. W. Monier-Williams, Dr. Albert Green, and Dr. Magnus Pyke on the committee, has been formed for the study of food in relation to health and disease. Its scope will include the production, processing, and distribution of food for both human and animal consumption, and the manufacture and control of preparations for supplementing diets for medical use in the nutritional disorders. Membership is open to all members of the Society of Chemical Industry and the Food Group, and regular meetings are being arranged for the New Year. The work began at a recent meeting of over fifty chemists and other research workers in London, when the committee was elected and an informal discussion on "Nutritional Problems of Exploration and Nutrition at High Altitudes" took place. The proceedings of the meeting will be published in the *Journal of the Society of Chemical Industry*.

Dr. Walter Elliot, Minister of Health, will visit Manchester on January 20 to open the new orthopaedic and physiotherapeutic building at the Royal Infirmary.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

CIRCUMCISION

BY

KENNETH WALKER, F.R.C.S.

Circumcision is probably the oldest operation in the history of humanity. It is also one of the simplest surgical procedures that the practitioner may be called upon to carry out. Nevertheless, in spite of its simplicity it is sometimes ill performed, and when this is the case may be followed by unfortunate complications.

Indications

The chief indication for the operation is the existence of a phimosis. This is usually congenital in origin, but may also result from contraction of the foreskin following repeated attacks of infection. Acquired phimosis is also very commonly met with in elderly men who have not paid enough attention to hygiene, and have failed to withdraw the foreskin and wash away smegma. In such cases repeated attacks of balanitis and posthitis carry with them a considerable risk of carcinoma, and to remove this risk, circumcision is urgently indicated. In younger patients phimosis may be a complication of a venereal infection. A patient with a long foreskin is far more likely to suffer from balanitis and posthitis if he contracts gonorrhoea than one who has been circumcised, and, should these complications occur, treatment by means of irrigation may be rendered very difficult. Statistics also show that the incidence of syphilis is higher among the uncircumcised than among the circumcised. This is due not only to the greater difficulty in carrying out satisfactory prophylaxis, but also to the fact that coitus with a tight foreskin is liable to cause minute lacerations through which the spirochaete finds a ready entry.

Because of the disabilities that may arise in later life, circumcision should always be carried out in an infant with a congenital phimosis—that is to say, with a prepuce that cannot easily be retracted over the glans penis. It is also sometimes advisable when the prepuce is redundant, even if retraction is possible. Since, however, phimosis is a relative term, there exist many intermediate cases in which doubt will be felt whether circumcision is or is not necessary. For these intermediate cases the compromise of stretching the prepuce may be all that is necessary. This is carried out by inserting artery forceps into the mouth of the prepuce, which has been smeared with petroleum jelly, and then opening them so as to stretch the orifice sufficiently to allow of its easy retraction. The nurse can then be told to withdraw the prepuce daily, wash the glans penis with a mild antiseptic, and cover it with a thin layer of petroleum jelly. By such means the necessity for circumcision can often be avoided. Care, however, must be exercised to make sure that the prepuce has been entirely withdrawn, since its mucosa is often very adherent to the surface of the glans, and complete separation may not have been effected. In older children circumcision is sometimes advised in the treatment of such conditions as enuresis or masturbation. Personally I have never seen any benefit result from circumcision in cases of enuresis. It is, however, a justifiable measure in confirmed masturbation when there is reason to believe that the long foreskin is a source of irritation.

Anaesthesia in Circumcision

In the infant no anaesthetic is necessary. For children a general anaesthetic is indicated, but for adults local anaesthesia is sufficient. The nerves to the outer layer of the prepuce may be blocked by injecting 30 minims of a 0.5 to 1 per cent. solution of novocain, with or without adrenaline. The nerves to the inner layer of the prepuce are caught by infiltration as close to the corona as the needle can be inserted. When it is difficult to reach this position because of the impossibility of retracting the prepuce, the same object may be achieved by injecting the solution into the upper quadrant of each corpus cavernosum. In this case, however, anaesthesia may not be complete in the region of the fraenum, and additional local infiltration here may be required. Five to fifteen minutes are necessary for the novocain to take effect. Anaesthesia as a rule lasts forty-five to sixty minutes.

It should be borne in mind that psychologists are disposed to lay great emphasis on the psychological trauma that may result from the carrying out of circumcision in children. Care should therefore be exercised not to frighten a nervous child; and generally it is advisable to make use of some such basal narcotic as nembutal, paraldehyde, or avertin.

Technique of Circumcision

The commonest method is by means of a clamp. The foreskin is pulled forwards, and a circumcision clamp (of which there are many varieties) is placed obliquely on it parallel to the corona glandis. The clamp is then held in the left hand and the foreskin and clamp are cut off with the scalpel, the edge of which is kept as close to the clamp as possible. The skin retracts and the mucous membrane is seen to be still covering the glans. The edge of this is picked up with forceps, cut along the dorsum to the corona, and stripped off the glans until the coronal sulcus is exposed. This redundant mucous membrane is then clipped away.

Simple as this procedure is, mistakes may easily be made, the commonest of these being to draw too much skin into the clamp. Should this be done it may be found

when the clamp has been removed that the skin withdraws half-way up the penis. For this reason the following method is preferable. The foreskin is first retracted until the surface is tense, and on the edge of it are placed three pairs of fine-toothed forceps, two on each side of the median line dorsally, and one at the middle line ventrally (see figure). These are raised, and the foreskin is separated from the glans with a director. With a sharp, pointed

pair of scissors the foreskin is then slit up the middle line of the dorsum as far as the coronal sulcus, the edge of each flap thus formed being held by one of the forceps. The flaps are well stripped off the glans, and from the end of the dorsal incision a second is carried round one flap of foreskin, leaving just a narrow ledge of mucous membrane below the corona. This flap is cut away, leaving the lower pair of forceps attached. The same incision is carried round the second side, this time cutting away the two remaining pairs of forceps. After removal of the forceps four bleeding points will usually be found—a dorsal, two lateral, and a fractional. If the bleeding from these does not quickly cease they are clamped and tied with fine catgut. Catgut stitches are then inserted through the mucous membrane and skin, bringing them into accurate apposition.

In children the wound should be thickly dusted with boric powder, no dressing being necessary. In adults a dressing of moist antiseptic gauze or of acriflavine in liquid paraffin should be wrapped round the line of suture.

Complications of Circumcision

The commonest complications are (1) insufficient or incomplete removal of the foreskin, with subsequent contraction; (2) injury to the glans; (3) removal of too much skin when employing the clamp method; (4) sepsis; and (5) haemorrhage and the formation of a haematoma. It is unnecessary to discuss the avoidance of these, since they all point to an error in technique. It is, however, advisable to mention that in the presence of severe sepsis circumcision should be postponed until this has been reduced by proper treatment. This will consist either of preputial wash-outs or of carrying out a preliminary division of the prepuce along the dorsum. By slitting the prepuce in this manner drainage is improved and treatment by means of penile baths and the application of antiseptic dressings facilitated. All that it is necessary to do in order to complete the circumcision at a later stage is to remove the two flaps of prepuce lying on each side of the glans.

CONTROL OF PUERPERAL FEVER

LECTURE BY DR. L. COLEBROOK

A Chadwick Public Lecture was given at the London School of Hygiene and Tropical Medicine on December 13 by Dr. LEONARD COLEBROOK, honorary director, research laboratories, Queen Charlotte's Hospital. His subject was "The Control of Puerperal Fever."

Dr. Colebrook began by remarking that ten years ago progress in the campaign against maternal mortality was held up by lack of knowledge; to-day the difficulty was that more facts had been accumulated than it had been possible to put into practice. Infection of the genital tract must not be regarded as coming under a single category. Out of one hundred cases of puerperal fever about forty would be found brought about by the haemolytic streptococcus, and the other sixty by different organisms, mostly following a certain amount of injury during labour. These two groups differed in their aetiology, prognosis, and treatment, also to some extent in their pathology. He had little to say about the second group because until to a large extent injuries during childbirth could be obviated such infections would persist.

Infection by Haemolytic Streptococcus

The first group, due to infection by the haemolytic streptococcus, was the most important because the infections were the most serious and the most easily prevent-

able. It was now known that there were some six or seven different groups of the organism which could be distinguished by biochemical and serological tests, but only one of these groups was responsible to any large extent for puerperal fever. In all cases the streptococci were found in abundance in discharges from the mother, and the task of research had been to find out from whence the organism came, and why one woman out of one or two hundred got it and the others escaped. It might be transferred from other cases of septic infection through the doctor or nurse; it certainly did come by way of the air in particles of dust or droplets from the throat, which was the most important source. Dr. Dora Colebrook had investigated forty-eight cases in which she had been able to identify the organism found in the mother with that from some outside source. In twenty-four cases the infection had come from an attendant contact—that is, doctor, nurse, or midwife—and of the twenty-four all but one were respiratory; of the others, nine came from a member of the mother's household and six from the mothers themselves.

The question whether so-called healthy throats were dangerous had been considered in relation to this work. Research had shown that sometimes these might be a source of infection. There seemed to be something like 5 to 10 per cent. of people who were carriers of this group of streptococci. Nasal infections appeared to be less frequent, but when these did occur they were often more serious, because a person suffering from a sinus infection always had a little discharge and only a small degree of lack of care was necessary for the infection to be carried.

Preventive Methods

With all these possibilities it was difficult to get complete safety in midwifery. The ideal would be to inoculate all women in the last month of pregnancy, but at the moment this was not in sight. Many other things, however, could be done. It should be possible to erect barriers by the wearing of efficient masks and the use of strict antiseptic toilet. Some valuable things had been learned with regard to antiseptics during the last few years. The prime importance of soap and water had been established. There was no doubt that this was the most valuable antiseptic ritual in both surgery and maternity work. It had been useful to find out that the old antiseptics, which had been chosen rather at random, did not give a sufficient margin of safety when removing streptococci from the skin, and it had been shown that iodine and the halogen derivative of xylene known as "dettol" were much better in this respect. They left a protective film on the skin which lasted a matter of hours, and this should be of value in dealing with prolonged labour. Dettol had been used at Queen Charlotte's for the last five or six years. There was a danger now that with the introduction of prontosil less trouble would be taken over this strict ritual, but it should be remembered that there were a few streptococci which were not susceptible to these agents, and there was nothing to prevent them from becoming virulent and an epidemic starting if antiseptics was relaxed.

But whatever the barriers, maternity policy ought to be so shaped that the fewest possible number of women were delivered in a dangerous environment. As to whether it was better for women to have their confinements at home or in an institution, in four years at Queen Charlotte's only one patient in 700 had developed the haemolytic streptococcus infection, whereas on the district the incidence had been 1 in 115. The same results had been shown at University College Hospital, London, and the Elsie Inglis Hospital, Edinburgh. It was quite certain that within the next few years, with more known about the sources of infection, it would be possible to get most of the maternity hospitals up to that standard, whereas it was not at all certain that even with better houses and improved economic conditions the figure, so far as the homes of the mothers were concerned, would be very much better.

Institutional Midwifery

More midwifery should be carried out in properly planned and conducted maternity institutions. By "properly planned" he meant either an institution separate from a general hospital, with its medical and surgical wards, or, if associated with a hospital, sufficiently segregated both in space and staff to prevent any possibility of infection passing by way of air currents, nurses' clothing, and the like. By "properly conducted" he meant what he called an "antiseptic precaution service," a definite schedule of preventive measures carefully thought out and aimed at preventing the spread of the streptococci. When engaging new staff throat swabs should be taken. Acute respiratory infections, including colds, should be carefully investigated, and sufferers kept from work until the bacteriologist reported that no streptococci or pneumococci were present. Probably the most common mistake in obstetrics to-day was failure to investigate puerperal cases until the fever had continued for some days. The idea seemed to have got abroad that a swab should be taken from the cervix uteri with the aid of a speculum, but this was not necessary; if the patient had the streptococcus suspected it would be found in the vagina.

Dr. Leonard Colebrook ended with a short account of the results of penicillin and sulphamylamide therapy in puerperal fever. Since penicillin was first administered at Queen Charlotte's the death rate had dropped to a remarkable extent. There could be no doubt that these drugs had changed the whole outlook. If the same thing took place in other hospitals it would mean that the hæmolytic streptococcus would cease to be an important factor in maternal mortality, although it would be always necessary to work under the threat of it.

Dame Louise Mellroy took the chair at the lecture, and the vote of thanks was proposed and seconded by Professor H. Miles Phillips and Sir Ernest Graham-Little, M.P., respectively.

PHARMACY AND POISONS ACT, 1933

AMENDED RULES AND SCHEDULES

The Poisons (Amendment) Rules, 1938, and the Poisons List (Amendment) Order, 1938, which were made by the Home Secretary on December 15, will come into operation on January 1, 1939. The following changes should be noted.

First Schedule Poisons

Rule 7(4) of the Poisons Rules, 1935, has been amended so as to provide that a signed order for a First Schedule poison (not being a poison to which the Dangerous Drugs Acts apply) given by a duly qualified medical practitioner, registered dentist, registered veterinary surgeon, a hospital, infirmary, dispensary, or clinic, need not contain a statement of the purpose for which the poison is required if the seller is reasonably satisfied that the poison is required for the purpose of medical, dental, or veterinary treatment.

New Methods of Labelling

Rule 17 has been re-enacted with amendments to permit the following new methods of labelling:

(2) When a poison is named specifically in the Poisons List and is the subject of a monograph in the *British Pharmacopœia* or the *British Pharmaceutical Codex*, one of the names at the head of the monograph in the *Pharmacopœia* or the *Codex*, as the case may be, may be used to describe the poison instead of the term in the Poisons List.

(2) A substance which is the subject of a monograph in the *British Pharmacopœia* or in the *British Pharmaceutical Codex* and any dilution, concentration, or admixture of

such a substance may be named with the name used to describe the substance in the *Pharmacopœia* or in the *Codex* with the addition of the letters B.P. or B.P.C. as the case may be. The similar provision already applicable to preparations, and to dilutions or admixtures of such preparations, in the *Pharmacopœia* or in the *Codex* is now extended to concentrations of such preparations.

(3) In the case of a preparation containing a poison mentioned in the first column of the Sixth Schedule to the Rules it will be sufficient, where the name of a poison or substance is mentioned in the relevant particulars in the second column of that schedule, to state the name of that poison or substance.

(4) In the case of preparations derived from nux vomica or from opium and containing one or more alkaloids of nux vomica or of opium named in the Poisons List, it will be sufficient to use the name "strychnine" or "morphine," as the case may be, or one of the names or abbreviated names of strychnine or morphine as the case may be, set out at the head of the monographs in the *Pharmacopœia* or the *Codex*.

Substances are now included with preparations and surgical dressings in the provision contained in Rule 18(3) that, where they are named in accordance with Rule 17(2), the proportion of poison contained in them need not be stated on the label. The provisions of the same paragraph as to the method of expressing the proportion of poison in a dilution or admixture of a preparation so named are now extended to concentrations of such preparations, and to dilutions, concentrations, and admixtures of substances so named.

Other amendments to Rule 18 and to the Sixth Schedule enable the proportion of the poison in preparations containing nux vomica or opium, and in preparations derived from nux vomica or from opium and containing one or more alkaloids of nux vomica or of opium named in the Poisons List, to be stated in terms of the proportion of strychnine or of morphine respectively. A further amendment to the Sixth Schedule enables the proportion of insulin in a preparation to be stated in terms of units of activity as defined in the *British Pharmacopœia*.

Benzedrine and Sulphonamide

Benzedrine and related substances (except when contained in inhalers—see next paragraph) are included in Part I of the Poisons List and also in the First Schedule and paragraph 1 of the Seventh Schedule to the Poisons Rules. Sulphonamide and related substances are included in Part I of the Poisons List and also in the First and Fourth Schedules to the Poisons Rules.

Additions have been made to the special exemptions in Group II of the Third Schedule to the Poisons Rules, to exempt from all control under the Act and Rules benzedrine and related substances contained in inhalers, and dinitrocreols in substances other than preparations for the treatment of human ailments.

By an amendment to Rule 22(1)(b) glass bottles containing local anaesthetics for injection in the treatment of human or animal ailments will no longer be required to have a fluted outer surface.

Copies of the Order (price 1d.) and Rules (2d.) may be purchased from H.M. Stationery Office or through any bookseller.

Crippled for life through a fall at the age of 15 John Pounds, Portsmouth shoemaker and originator of the idea of ragged schools, the centenary of whose death occurs on January 1, in interrogatory and realistic fashion taught the poorest children in his town the rudiments of knowledge, how to cook, mend their own shoes, and make their own toys. Besides being their voluntary schoolmaster, he acted as their doctor and nurse. His influence was recognized after his death, when schools were founded in his memory.

ONE HUNDRED AND SEVENTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION ABERDEEN, 1939

THE one hundred and seventh Annual Meeting of the British Medical Association will be held at Aberdeen next summer under the presidency of Dr. Thomas Fraser, consulting physician, Aberdeen Royal Infirmary. The Sectional Meetings for scientific and clinical work will be held on Wednesday, Thursday, and Friday, July 26, 27, and 28, the morning sessions being given up to discussions and the reading of papers. The Annual Representative Meeting for the transaction of medico-political business will begin on the previous Friday, July 21. The titles of the Sections with the names of the presidents of each Section appear in the *Supplement* this week (p. 407). Further details of the Section officers and of the general arrangements for the Annual Meeting will be given in subsequent issues. We publish below the first of a series of descriptive and historical articles on Aberdeen and its medical institutions.

ABERDEEN TO-DAY

BY

ALEXANDER KEITH

Town House

ABERDEEN to-day in spirit is the Aberdeen of yesterday, of eight centuries of yesterdays; but its main outward appearance is that of a modern city. Few of its buildings can claim to be of venerable age, yet it is still, as it was in Edward I's time, "a good town upon the sea," and its business is still, as at the Restoration, concerned with "salmond, coarse woolen-cloth called playding, linning cloth, stockines, skins, hydes, and all that the country yields," though it has added several strings to its industrial bow since then. Its inhabitants, not being given much to poetry, may not express their civic sentiments by quoting Dunbar's lines:

Unto the heaven ascended thy renown is
Of virtue, wisdom, and of worthiness;

but that, in substance, is what they think.

For a generation or two Aberdeen seems to have acquired and kept, among the lesser breeds (who inhabit, to the certain knowledge of every responsible Aberdonian, all the world beyond a circle of twelve miles' radius round Aberdeen), the reputation of being a city "pour rire." Recently a contingent of German schoolboys about to make a trip to this country were advised by a Teutonic pundit that they need not include Aberdeen in their itinerary as it was only a small fishing village. In the description the word "fishing" is correct. For the rest, Aberdeen is in point of population the third city in Scotland, the Registrar-General's latest figure being 178,200 souls. It is the most northerly of the cities of the British Empire. It is probably as wealthy per head of population as any in the United Kingdom. It adds to a remarkable variety of industries a unique educational equipment. Its annual record of sunshine is higher than that of any of the British "resorts," and its average summer temperature is only three degrees below that of the English Channel coast. Its trade—as distinct from its consumption—in food, "stored sunshine," is easily the largest of any British centre.

First seen from the south by those arriving by rail, Aberdeen is not prepossessing; no town is if thus entered. The railway approach is through the chief industrial

district, and all industrial districts are alike in appearance. But if the arrival is by road, Aberdeen at first sight reveals a sufficiency of charms to the visitor while he is yet afar off. The River Dee, emerging from the wooded spurs of the mountain range called the Mounth, still marks what is practically the southern boundary of the city. To the right is the sea, studded with cargo boats and trawlers plying to and from the port. To the left are the residential suburbs. In the left centre, lifted above the city and gleaming white on its hill, is the great new Royal Infirmary. In the right centre rise innumerable spires and towers above the busy haze. It used to be said of Aberdeen, as of Rome, that it was built on seven hills, but the Aberdonian requires more elbow room as he expands with prosperity and progress, and during the last twenty years other hills have been incorporated into the town to accommodate upwards of 10,000 new houses built since the war. Not the least interesting of these new hills are the two, named Tullos and Kincorth, on the approaching wayfarer's right before he crosses the Dee to enter the city. These have been acquired by the corporation, and upon them will in due time be laid out a satellite town, an industrial suburb, a golf course, and other amenities.

City of Open Spaces

Aberdeen is no congested area. It covers 11,000 acres, with a population density of sixteen per acre. Its open spaces, including fifty-eight acres of children's playgrounds, extend to 1,733 acres, comprising the town's links; the beautiful Hazlehead estate with its 200 acres of woodland and a magnificent collection of rhododendrons; the Duthie Park, which contains a winter garden; other public parks, three public golf courses (besides four 18-hole private courses in or near the city); and ground for football, cricket, bowls, tennis, and hockey. Its forty-two schools provide accommodation for over 33,000 pupils. There are two nursery schools for infants between the ages of 2 and 5; two special schools for mental and physical defectives; and over a dozen play-centres open three nights a week with average attendances of 3,000 a night. Some 4,000 children are educated at four secondary schools, as befits a university city. (The University of Aberdeen, and the health services, with which the University's Medical Faculty is closely linked, will be dealt with in subsequent articles.)

Although to the casual observer Aberdeen may seem to be inhabited principally by lawyers, doctors, and bankers, Aberdonians have other occupations. Chief among the industries which sustain the city is agriculture. Over £2,500,000 represents the annual turnover in livestock in Aberdeen; every week 1,000 cattle and 3,000 sheep are slaughtered in the city, while a bacon factory six miles out can cope with 3,000 pigs a week. Aberdeenshire feeds more commercial cattle than any other three counties in Scotland; it has twice as many pigs as any

county in Scotland; it grows one-fifth of Scotland's total crop of oats; every day the city's population consumes nearly 10,000 gallons of milk, yet a surplus of several thousand gallons daily remains to be sent south; the county's output of potatoes is equal to twice the general British average; it raises one-tenth of Scotland's yield of straw-

berries; it is among the six chief vegetable-growing counties in Scotland; the beekeepers' association that has its headquarters in Aberdeen is the largest in Britain; while as testimony to the genial character of the city's supposedly hyperborean climate, it may be mentioned that one gardener within its bounds can shelter under his own fig-tree and eat the fruit thereof, and another was plucking ripe strawberries in November. Thousands of tons of meat, oats, oatmeal, and potatoes are sent by sea, rail, or road from Aberdeen annually.

The Fishing Port

Next to agriculture comes fishing, the white and, to a limited extent, the herring fishing. The annual value of the fish landed at the port is £1,000,000; in its peak year it was £3,000,000. Aberdeen then was the leading white-fish port in the kingdom; now it is third. Its fleet of over 300 trawlers and liners, employing 3,000 fishermen and 9,000 shore hands, specializes in short voyages and quality fish. The fish market is the chief industrial "sight" of the city. It is nearly half a mile long, and at 8 o'clock in the morning, as a "shop window" for the white fisheries, it is worth a visit. The fishing gives employment to a great many subsidiary industries, such as the making of nets, of ice, of boxes, of lacquer for the inside of tins, besides the preserving of fish in various ways, the extraction of cod-liver and halibut-liver oils, and the manufacture of fish meal from offal. In connexion with

agriculture and fishing there is a concentration of scientific research in Aberdeen: for agriculture the North of Scotland College of Agriculture, the Rowett Institute (mainly engaged on nutrition), and the Macaulay Institute for Soil Research; for fishing the Research Station of the Department of Scientific and Industrial Research and the

Marine Laboratory of the Scottish Fishery Board.

Aberdeen is the "Granite City," and despite fluctuations in fashion the quarrying and handling of granite is one of its staple trades. The output from the quarries is about 400,000 tons yearly, and among many buildings of Aberdeen granite outside Aberdeen may be mentioned Thames House, Imperial Chemical House, and the Carlton Club in London; St. George's Hall, Liverpool; King Edward VII Bridge, Newcastle; and the new Government

Buildings in Edinburgh are being faced with it. In Aberdeen itself Marischal College and the new Royal Infirmary are testimony to its elegance and beauty. Another side of the industry is the monumental trade, which became active when, a century and a quarter ago, an Aberdeen granite merchant rediscovered the ancient Egyptian method of polishing the stone. If with its fish and its meat Aberdeen caters for mankind living, with its tombstones it immortalizes mankind dead.

Variety of Industries

Paper-making has flourished in Aberdeen for 200 years; one of its mills is the largest in the country. Textiles in Aberdeen have had a still longer history, and to-day two of its factories employ over 1,000 hands each. A woollen mill produces 19,600 miles of yarn a day. Tweeds, woollen stockings, gloves, underwear, blankets, wineys, tarpaulins, and hose-pipes are among the lines that have been long or recently developed. Of three shipbuilding yards, one specializes in passenger and cargo steamers, one in dredgers, hoppers, and tugs, and another in cargo boats.

Aberdeen Union Street from the Air

Brig o' Balgownie

The first Diesel electric tug built in Britain came out of an Aberdeen yard. From Aberdeen engineering shops have gone cableways that are now working in the Pacific; cranes for Egypt, India, and West Africa; milling and crushing plant for Burma, Malaya, East and West Africa, and Central America. An important branch of the industry is agricultural machinery and implements, while the invention of the cold-starting Diesel engine in Aberdeen has resulted in the production by the city of great quantities of these engines.

Combs, soaps, paints, chemicals, fertilizers, iron grit, confectionery, organs, baskets and brushes, pneumatic tools, calendars, surgical appliances, drugs, and furniture are other industries which indicate that the city does not stick to one basket, even of its own making, for all the eggs it handles.

Architectural Variety

Architecturally Aberdeen, if not outstanding and although to the stranger the predominant granite seems hard and cold, has a few specimens to show. The bridge which carries the road from the south over the Dee into the city was completed in 1527. A new bridge to relieve the veteran is now being built a few hundred yards down the river. The old bridge over the Don, the Brig o' Balgownie, was built about 1320; it is a piece of sheer loveliness spanning a black and craggy pool of the Don (which, incidentally, is a far more picturesque river than its much-vaunted neighbour the Dee). The two rivers are connected through the centre of the town by three long streets: Holburn Street, Union Street, and King Street. Union Street, a mile in length, is the principal thoroughfare, the construction of which plunged the city in bankruptcy a hundred years ago. The strikingly bold design of the Town House, the Corinthian style of the North of Scotland Bank beside it, the ornate Hall of the Seven Incorporated Trades, the massive solidity of the Northern Assurance Buildings, and the Grecian aspect of the Music Hall, together with several examples of modern architecture in Union Street, show that Aberdeen's taste in buildings is as catholic as its choice of industries. Off Union Street, but visible from Union Bridge, the Public Library, the South Church, His Majesty's Theatre, the War Memorial, the Cowdray Hall, the Art Gallery, the School of Art, with Robert Gordon's Colleges behind the last two, form an imposing stretch of contrasted and beautiful frontages.

Some Celebrities

Between the Union Bridge and the Town House, and separated from the street by an Ionic façade, lie the graveyard and the twin churches of St. Nicholas. In the churches many of the city's treasured relics are preserved; in the graveyard are buried many of Aberdeen's eminent men and some strangers, among them one of the several husbands or lovers of the wife of Prince Talleyrand. There are more relics of Aberdeen's chequered past in the Trades Hall, both colleges of the University, the Public Library, St. Machar's Cathedral, in Old Aberdeen between King's College and the Brig o' Balgownie, and in the Town House itself. It is a strange coincidence that the owners of two of the most illustrious names in Aberdeen's Roll of Freeman should now lie together, though separated by a century in their lives, in the Haliburton Aisle of Dryburgh Abbey—Walter Scott and Douglas Haig.

Such in skeleton is Aberdeen to-day, bounded on north and south by the twin rivers Don and Dee, on the west by the woods and the fertile farmlands, on the east by its two long miles of golden sands and the sea. Its motto is "Bon-Accord"; its toast to the stranger within its gates is cordial: "Happy to meet, sorry to part, happy to meet again"; its air is bracing; its viands were full of vitamins long before science discovered them. Said Dr. Johnson (another of its Freeman) of the city: "The houses are large and lofty, and the streets spacious and clean"; and of his inn: "A very good house and civil treatment." So was Aberdeen, and so it is.

Nova et Vetera

J. B. MURPHY

Surgeon Extraordinary. The Life Story of Dr. J. B. Murphy, the Stormy Petrel of Surgery. By Loyal Davis. (Pp. 287; frontispiece. 8s. 6d. net.) London: George G. Harrap. 1938.

This account of J. B. Murphy of Chicago by Dr. Loyal Davis, professor of surgery and chairman of the division of surgery in the North-Western University of Illinois, is written attractively and will be welcomed by all who knew "J. B." It will be read with especial interest by British surgeons, who will compare his career with that of his contemporaries, Sir William MacEwen in Scotland, John McArdle in Ireland, and Lord Moynihan in England. All were self-made men, all became eminent as surgeons, and all had remarkable personalities; but their training and opportunities were wholly different. Of the four, Murphy began life with the heaviest handicap. He was the youngest son of a peasant driven out of Ireland by the potato famine of 1845, who was so poor that he worked his way to the United States as stevedore and sailor. He had the good fortune to marry another emigrant from Ireland whose family was in rather better circumstances, and to his wife Jolin Murphy owed much, for she was a woman of sterling honesty and of great common sense. J. B. Murphy's early years were spent in helping to clear the land which his father had bought at two and a half dollars an acre. For a few months he was a school teacher, then he became assistant to a druggist in the village shop, and, as handy boy to a friendly doctor who appreciated his ability, he was led towards medicine. Murphy entered the Rush Medical College at Chicago after much consideration, although the fee was fifteen dollars more than that of the Chicago medical school, qualified, and became an intern at the Cook County Hospital. Of the medical education and of the hospital practice Professor Loyal Davis gives a very lively account without exaggerating the facts. Thanks to his mother's economy, but with very straitened means, Murphy was enabled to spend some months first in Vienna, then at Heidelberg, and on his return to Chicago became a partner with Dr. Ed. W. Lee, who had a practice in the city. Here he married a charming, sensible, and pretty girl who came of a well-to-do family. She made him an excellent wife, was his constant companion, advised him always for the best, and did much for his social education.

The Haymarket Square riot at Chicago in May, 1886, resulted in many gunshot wounds and turned Murphy from a family doctor into an operating surgeon. From that time onwards he specialized in abdominal operations, became known throughout the world for his "short-circuiting" by means of the "Murphy button" and by his advocacy of early operation in appendicitis.

Professor Loyal Davis gives an unbiased account of a man who was never accepted cordially by his colleagues, partly because they were envious of his success, partly because Murphy was himself difficult and loved to be in the limelight, and partly because he retained to the end many traits of his peasant origin. The story is told well but rather too flamboyantly, and is full of personal details. Those who begin to read it will not stop until the last page is reached, and by that time they will have learnt how a remarkable man rose from being a pioneer on the land to become a pioneer in surgery. A portrait, which is an excellent likeness, is supplied as a frontispiece.

MALARIA IN ENGLAND

Dr. W. H. M. Wilson writes from Burnham-on-Crouch, Essex:

Where the North Sea washes the eastern coast of Essex there is a strip of land five miles broad and ten miles long which lies under the level of the high tide and is protected

from the sea by a stone wall. Although this land is efficiently drained it is still called the Marshes. Fifty years ago it was all cornland, but now it serves as a rich pasture to herds of milking cattle.

In this area and in the villages round about there still lives a generation of men and women who can remember malaria in England. The ague, they call it. As they are all about eighty years old now, the day cannot be far distant when they and their memories will be gone. For this reason it is perhaps worth recording the account of an old man to whom I was speaking the other day. After all these years it is doubtful if it could be accurate, but is nevertheless interesting.

This ancient now lives at Burnham-on-Tonch, but seventy years ago, when he was nine years old, he lived at Staminate on the Blackwater. It was then that he had the ague. He still remembers the terrible coldness, as he sat over the fire with his teeth chattering, and how his mother used to put rugs round him to try to get him warm. Soon afterwards he would be just as hot. According to his account it would first come on one day and then miss one, then two days and miss one, then three days and miss one. As time went on, however, it would get less frequent, until it only came on every now and again. Apparently ague was largely a disease of children, as he says that most of the children had it, and the adult population only used to get an occasional attack. It was severe enough to keep him away from school for six months. The people had no idea of the cause, and there was evidently little in the way of treatment—for the poor at any rate. Groundsel made into a pad and slept on was one of the remedies employed, without much effect. The disease, according to my informant, had been in existence for very many years, but died out soon after this, and not much has been heard of it since. He believed there was a Government grant for the provision of quinine.

It occurs to me that as London is built on the westward continuation of these same marshes up the Thames estuary the disease may have been endemic there also. Perhaps there are practitioners alive still who worked in Poplar, Limehouse, Lambeth, Vauxhall, or other low-lying districts round the river seventy years ago who could tell us something about it.

ANNALS OF MEDICAL HISTORY

Of the eight main articles in the September number of the *Annals of Medical History*¹ half are short biographies. Professor Ralph Major of Kansas City, whose *Classic Descriptions of Disease* are in such constant use by those who like to verify their references, writes on Santorin Santorio, whose *Statia Medicina* produced such a sensation in the medical world, went through twenty-eight Latin editions, and won him the title of "the father of the science of metabolism." In a well-illustrated article on Sir Hans Slane, Dr. Burton Chance of Philadelphia, who has previously written on the founder of the British Museum, reproduces an interesting advertisement of Sloane's milk chocolate, stated to be of "great use in all consumptive cases." Sir Robert Armstrong-Jones in a pleasant account of Keats and his friends draws welcome attention to Keats's house, Wentworth Place, Hampstead. A. P. Borodin, physician, chemist, and musician, is described in an extremely interesting manner by Dr. Sunderman. The early teachers—Alibert, Biett, Cazenave, Devergie, and Bazin—at l'Hôpital Saint-Louis, Paris, and their influence on American dermatology are passed in review by Dr. P. E. Hechet of New York. Dr. Gibson writes on the captured medical men and army hospitals during the American revolution; Dr. E. M. Jameson gives an account of obstetrics and obstetricians in the United States during the eighteenth century; and Dr. Solomon R. Kagan, whose *Life and Letters of F. H. Garrison* is reviewed in this number, contributes a short essay on Maimonides' prayer.

¹ *Annals of Medical History*. New Series, Volume X, No. 5, September, 1938. Edited by Francis R. Packard, M.D. (Pp. 369-462; illustrated. Subscription for year, 11 dollars; single number, 2.50 dollars.) New York: Paul B. Hoeber Inc.; London: Harper and Brothers, Book Department. 1938.

HEALTH OF THE SCHOOL CHILD

CHIEF MEDICAL OFFICER'S REPORT

Sir Arthur MacNalty's report as Chief Medical Officer of the Board of Education for the year 1937* consists of an introduction, sixteen chapters, and a series of appendices. It is a composite document, the work of many hands. With the issue of this report the School Medical Service celebrates its thirtieth birthday, and Sir Arthur MacNalty traces its origins to the nineteenth century, when great humanitarians like Lord Shaftesbury fought to bring some health, beauty, and learning into the lives of children hitherto condemned to the unrelieved gloom of the factories. When, in the 'seventies, education became the business of the State, the need for medical supervision of the children became more obvious, and in 1891 the London School Board appointed a medical officer. In 1907, after various investigations which had revealed how badly it was needed, the School Medical Service proper was established by the Education (Administrative Provisions) Act. From its beginning it has been a part of the Public Health Service of the country. When the Ministry of Health was established in 1919 the links were drawn closer by the appointment of Sir George Newman to be Chief Medical Officer of the Ministry of Health, while at the same time retaining the post of Chief Medical Officer of the Board of Education; and his successor has continued the two-fold functions.

Nutrition of the School Child

Once again nutrition is given pride of place in the report. The year 1937 was eventful from this point of view, for in its early part the first report of the Advisory Committee on Nutrition was published, and during the year large-scale inquiries under the aegis of that committee were continued. In addition a dietary survey, to be carried out by the Carnegie Trust under the direction of Sir John Orr, was inaugurated. The Board has consistently urged the great importance of a sufficient quantity of milk as in most cases the key to the improved nutrition of the school child. But the qualification "in most cases" must be noted, for some school children need solid meals either alone or in addition to the extra milk.

During the year 1,696,527 children were assessed at routine medical inspections in respect of their nutritional state. The percentages placed in the four groups were as follows:

| | | | | |
|-----------------------|----|----|----|----------------|
| A. Excellent | .. | .. | .. | 15.0 per cent. |
| B. Normal | .. | .. | .. | 73.8 " |
| C. Slightly subnormal | .. | .. | .. | 10.6 " |
| D. Bad | .. | .. | .. | 0.6 " |

These percentages are practically the same as those found in the two previous years. Attention is drawn to the value of frequent weighing and measuring as an aid to the clinical assessment of nutrition. Certain criticisms of the method of clinical assessment are discussed and the conclusions reached are that:

(1) There is no accepted objective method of measuring nutrition.

(2) As a purely subjective method the clinical assessment of nutrition must inevitably lack scientific accuracy, and to criticize it as unscientific is but to beat the air.

(3) The absence of a satisfactory standard of normal nutrition is the explanation of the many divergent returns as to the nutritional condition of elementary school children.

(4) As a subjective method clinical assessment is dependent on the individual standard of the assessor.

(5) Clinical assessment of nutrition is fallible.

In these defects it resembles many other forms of assessment based on subjective methods, such as academic examination or medical diagnosis.

The great importance of securing that school children get enough sleep is emphasized once again, and the

* H.M. Stationery Office, price 2s. 6d. (by post 2s. 8d.).

section closes with a summary of recent work on vitamin deficiencies in children's diet.

Provision of Milk and Meals

During 1937 there was an increase of 4 per cent. in the proportion of children taking milk in public elementary schools and an increase of about 2 per cent. in the proportion of school departments in which the milk-in-schools scheme was in operation. While these figures are a slight improvement, it is hoped that the national campaign for the increased appreciation of the health services which began in the last month of 1937 will show a greater improvement in 1938. Progress in schemes for the provision of solid meals for school children, both free and for payment, is reported, and an appendix deals with "school canteens" which cater, chiefly in rural areas, for children who have to come a long way to school.

The interim report of the Milk Nutrition Committee is discussed. Though the results of these large-scale investigations into the value of an extra ration of milk are not quite so striking as those of certain former investigations, the children receiving milk showed an obvious benefit when compared with the controls. No constant difference was observed between the growth rates of children receiving raw milk and of those receiving pasteurized milk.

Physical Education

A great obstacle to the progress of physical education in schools has been the lack of adequate facilities for carrying out comprehensive schemes of training, but much is now being done to remedy this state of affairs. A recent development in London is designed to overcome the difficulty of great distance between school and playing field. A number of large playing fields have been equipped with classrooms, so that it is possible to send whole groups of children to the playing field for a whole day. During the day each class has at least an hour for games and spends the rest of the day in more academic work.

Infectious Diseases

Early in 1938 the first report of the Epidemics in Schools Committee was published, and although this committee is concerned with boarding schools for the most part and its investigations are as yet at an early stage much interesting information has been accumulated. Sir Arthur MacNalty discusses the problem of the administrative action taken to control infectious diseases in school children and concludes that in the present rapidly changing state of medical knowledge it is wiser to defer any revision of the policy of the Board of Education and the Ministry of Health. While the incidence of infectious diseases has not markedly decreased of recent years, the mortality from them has decreased considerably. For example, the death rate from measles at ages under 15 years per million living decreased from 750 in 1910 to 143 in 1935.

Medical Inspection and Treatment

The work of routine medical inspection and treatment is described. For the first time the statistics of the incidence of defects allow a fair comparison to be made between the incidences in the various age groups. When defects of vision, defects of nutrition, uncleanness, and dental disease are excluded, the entrant group shows 15.7 per cent. with defects requiring treatment, the second age group 12.6 per cent., and the third age group 10.2 per cent. These figures bring out the reduction in the incidence of defect as the child passes from the age of 5 or thereabouts to the age of 12.

The provision for transfer of information from the School Medical Service to insurance medical practitioners made in the National Health Insurance (Juvenile Contributors and Young Persons) Act is described. A total of

1,700,078 children, or 37.1 per cent. of those in average attendance, were inspected at routine inspections. Progress has been made in the provision of clinics, particularly in the provision of joint health centres which cater for pre-school children as well as for school children. Other subjects dealt with are the scope of treatment under the School Medical Service, middle-ear disease, medical inspection and treatment in secondary schools and in junior instruction centres, and child guidance.

Since 1935 the number of operations for the removal of tonsils and adenoids has continued to rise, and a review of the subject is therefore included. The general conclusions reached are that operation should be undertaken only when there are clear indications for it, and that the conditions under which the operation is performed should conform to a proper standard which embodies those laid down in the report for 1923, together with new conditions. There is evidence that these operations are often performed without adequate reasons and sometimes without full precautions against dangers and complications.

Later in the report a chapter is devoted to skin diseases, particularly scabies, plantar warts, and ringworm of the scalp; other chapters deal with the treatment of speech defects, squint, and the problem of the partially deaf child. The latter consists of a review of a report made by a committee of the Board. The care of delicate children and the care of young children are discussed in the sections devoted to open-air schools and nursery schools respectively. Minor orthopaedic deformities and the teaching of hygiene in training colleges are also considered.

The School Dental Service

An interesting feature of the report on the work of the School Dental Service is a comparison between the condition of the mouths of a number of children in an area which up till now has had no school dental service with the dental condition of a similar number of children in an area with an efficient service. The advantage of the children whose mouths had been properly cared for is striking.

Reports of Societies

INFECTIOUS QUALITY OF NEUROSIS

At a meeting of the Medical Society of Individual Psychology on December 8, with Dr. H. C. SQUIRES in the chair, Dr. ETHEL DUKES read a paper on the infectious quality of neurosis, which was concerned especially with the relationship between parents and children.

Dr. Ethel Dukes pointed out that heredity and constitution must first be taken into account in assessing the contributory factors in the neurosis of children. Even where the material and personal environment appeared to be all that could humanly be expected; where the marital relationships between the parents and their mutual management of the family were good; and where the other children were normal in every way, one child might be neurotic. In such cases the family history might throw light upon the hereditary aspect of the case. Anyone who had had much experience of newly born infants was acutely aware of their differing individuality from earliest life, and particularly of their idiosyncrasies of behaviour on first being put to the breast. Character could almost be foretold by the knowledgeable, and mothers of large families would recall how differently each child reacted to feeding and nurture. The reception of all phenomena would be coloured or distorted by the interpretation the child made to himself of his early experi-

ences. Conflicts then might arise and, however wise authority might be and however stable the environment, unless the child could correlate his experiences and resolve his own emotional conflicts he was bound to suffer. There were, on the other hand, children who appeared to have inherited such psychological tendencies to stability that nothing, not even the most unstable environment, could upset their serenity. These children were not necessarily stupid or dull. Many, on the contrary, were gifted individuals, often lively and possessed of a good sense of humour, in addition to the capacity for getting on well with others.

Need for Security

The most important factor in the early normal development of childhood was a sense of security in the fundamental relationships of life. So often in cases of neurosis in children was it found that one or more of the parents or close attendants suffered from neurotic complaints that the illness of the child seemed almost like an infection. Sometimes the symptoms were alike, but more often they differed, for a child's reaction was different from that of an adult. This was often unconsciously dramatized in play-therapy analysis. Hence the importance of family and environmental histories and the frequent necessity for treating some other member of the family in addition to the child.

In this earliest period of life the child, though a highly potentialized individual, lived largely in the unconscious. Life for him was chiefly that of affectivity, and whatever happened in the unconscious as well as in the conscious mind of his parent was bound to have great influence on his emotional development because of his close psychic connexion with the parent. Young children understood life chiefly through their sensations and their intuitions, and knew intuitively when the conduct of the nearest adults was based on fears, inhibitions, and repressions. They reacted not only to the adults' words and actions but to their unconscious motivations. Children might be brought up in very restricted and poor conditions, yet if from their early days they recognized intuitively the unconscious "goodness" and emotional stability of their parents all might be well with them also. Dr. Dukes gave examples to illustrate her thesis. The paper aroused a great deal of discussion, to which many of those present contributed.

MALARIAL ENDEMICITY IN AFRICA

At the December meeting of the Royal Society of Tropical Medicine and Hygiene, with the president, Colonel S. P. JAMES, in the chair, Dr. D. BAGSTER WILSON read a paper on the implications of malarial endemicity in East Africa.

Malaria Surveys in Tanganyika

Dr. Wilson gave a brief account of the results of malaria surveys in two groups of Bantu people in Tanganyika, the Digo and the Nyiramba. The fallacy of relying on the spleen rate alone as an index of the endemic state was shown; for, although the spleen rates were the same, a comparison of the parasite counts at different ages and at different seasons showed that there was a great difference between the two groups. This difference lay in the degree of immunity acquired, the first group being fully immune and the second only partially immune. The estimation of parasite infestation by counting parasites should be, although as yet it was not, pre-eminent as a method of field study. The lack of immunity was also revealed in the liability to clinical attacks of malaria, which were confined to infants in the Digo group, but were liable to occur at all ages in the Nyiramba. The factors responsible for the production of a full immunity were discussed, and it was concluded that the differences found

were explicable in terms of frequency of infection. In the Digo villages reinfection was liable to occur about thirty times a year, but in the Nyiramba only four to eight times a year. Moreover, in the latter case there was a considerable period during which transmission was absent.

The freedom, after infancy, from illness attributable to malaria, together with the intense anopheline infestation, seemed to make *laissez-faire* the policy of choice among the Digo. Treatment sufficient to save life should be offered for the infants, Dr. Wilson said, but he gave reasons for concluding that anopheline control was impossible under the circumstances and with the resources available. In the case of the Nyiramba the situation was very different, and treatment might have to be given at any age, since it was demanded by the people themselves. Treatment should, however, be minimal—a supplement to, rather than a substitute for, such immunity as was present. Anopheline control in an area in which malaria was seasonal was also a much more feasible proposition, and an attempt at control in such an area should be made.

There was an essential difference in the two cases, and while in the one the only rational policy would appear to be the maintenance of the natural defences in man, in the other defence against the anopheline vector was possible and should be tried. Conditions essential to the carrying out of the second policy were a seasonal transmission and close settlement of the land. In any case, a rational malaria policy demanded close study of selected areas in every type of country—a study that still largely remained to be made.

Acquired Tolerance

Professor R. M. GORDON, in opening the discussion, pointed out that the term "acquired tolerance" was a better one than "natural immunity." Too much importance could be attached to counting malarial parasites, as the number of parasites in the peripheral blood was not necessarily an indication of the total number present in the body. Thus a massive infection of the placenta might persist at a time when the peripheral blood appeared to be free from infection; similarly, cerebral malaria could be associated with scanty infection in the peripheral blood. Dr. Wilson had suggested that "curative treatment of either adults or infants in a hyperendemic area was to be avoided" because of the danger of interfering with acquired immunity. But how was an infant seriously ill with malaria to be treated in such a manner as to cure the symptoms but not destroy the parasite? The danger of failing to treat malaria in pregnancy was shown by the results of Blacklock and Gordon in 1925. Out of fifty-one children born alive of mothers with malaria-infected placentas 25 per cent. died. In a series of ninety-three children born of mothers whose placentas were not infected only 5.4 per cent. died within that period. In regard to the danger of curing malaria in the infant and thus postponing the acquirement of immunity, the work of Lourie on bird malaria, and Hackett's application of these results to human cases, suggested that rigorous quinine treatment did not interfere with the development of resistance to a fresh infection.

Lieutenant-Colonel J. A. SINTON said that Dr. Wilson had compared the degrees of immunity acquired by two tribes of the same race living under different conditions of severe malarial transmission. In areas where severe transmission was continuous reinfection and superinfection occurred without intermission throughout the year; this led in a few years to a condition of tolerance among the survivors to all the local strains of parasites. As a result the whole population, except those in the first few years of life, developed and maintained a high degree of tolerance: this was shown by the lower parasitic infestation and the diminution of clinical manifestations after the first ten years of life. On the other hand, where severe transmission was interrupted for many months of the year this overlap and superposition of infection and of its immunological effects was less common, so the

tolerance took longer to establish and its action was less constant and lasting. As a result morbidity continued, the parasite infestation remained at a higher level for a longer period of life, and clinical manifestations occurred. In regard to any immunity or tolerance to malaria in newly born or suckling infants, it seemed unlikely that this could be due to any specific antibody absorbed during lactation. More probably it resulted from transmission of immunity via the placenta or to an immunity acquired *in utero*.

General Discussion

Colonel C. A. GILL agreed with Professor Gordon that the term "tolerance" was a more exact description of immunity associated with hyperendemic malaria. Two types could be recognized. In hyperendemic areas with "complete tolerance" the adults had good physique, little sickness, no marked anaemia, a relatively low spleen rate, a low infestation index, and, according to Schüffner, a remarkably high birth rate and a low adult death rate. In hyperendemic areas with "incomplete tolerance" the afflicted natives were physical wrecks. Fever and anaemia were common, and the spleen rate and infestation index were both relatively high. The birth rate was extremely low and abortions were frequent, while the total death rate was relatively high. Dr. Wilson regarded frequent and constant infection as the main factor concerned in determining hyperendemicity with complete tolerance in Africa. While this might be one cause, it did not rule out a difference in racial reaction to infection, and in India "complete tolerance" was limited to aboriginal tribes or primitive tribes of great antiquity.

Dr. E. M. LOURIE spoke particularly on bird malaria and its bearing on human infections. He pointed out that in acute cases infection took place not because there was no natural immunity but because there was not enough of it or because acquired immunity had, for some reason or another, not sufficiently developed. Acquired immunity was really nothing more than an immunity to superinfection. The parasites were still present, but they were either below the threshold at which they could be seen, or if they could be seen they were not producing demonstrable clinical effects. This acquired immunity might at any time break down, giving rise to relapse.

Sir MALCOLM WATSON emphasized the difficulty of gauging fully the ill effects of malaria on a village unless one removed malaria from those people or removed them to a non-malarious area. Then the improvement was extraordinary. Where nothing else could be done—and at the beginning of a campaign nothing else could be done—infected people should be treated with quinine. Quinine would enable those people to develop an immunity; without quinine they died. Our conception of malaria control to-day included not merely malaria therapy and the control of mosquitos by drainage, species sanitation, and flushing, but the associated control of other diseases by biological measures, direct co-operation with agriculture in soil preservation, improvement in the soil, and preservation of the rainfall in countries where rainfall was deficient.

Colonel S. P. JAMES said that Dr. and Mrs. Wilson had made important improvements in technical methods for conducting a malaria survey. Instead of random sampling in the village street they had got to know the families in their homes, and watched infants and young children grow up through the various stages of parasitic infestation until complete or partial immunity had been maintained. Particularly interesting was their conclusion that the best guide to anti-malarial policy in these areas was the assessment of the number of parasites harboured by a community at different age periods and at different seasons of the year.

The Howard League for Penal Reform is calling a representative conference to be held in London during the last ten days of January to consider Sir Samuel Hoare's Criminal Justice Bill, which will reach committee stage in the House of Commons early in February when Parliament reassembles after the Christmas recess.

ENGLAND AND WALES

In Recognition of Work in Tropical Medicine

The Mary Kingsley medal, which was founded in 1904 to commemorate the work of Mary Kingsley (a niece of Charles Kingsley the novelist) for the welfare of the natives of West Africa, is awarded annually in recognition of services in tropical medicine. This year there were four recipients and, in addition, one honorary recipient, Lady Danson, and the medals were presented by Viscount Leverhulme, chairman of the Liverpool School of Tropical Medicine, at a reception held in the museum of the school. The recipients, who were introduced by Professor Warrington Yorke, were:

Dr. M. A. BARBER, whose many contributions to our knowledge of the mosquito and its habits include the discovery of the manner in which "Paris green," an arsenic compound, can be used as an effective and inexpensive means of destroying the larvae of malaria-carrying mosquitos. His long and distinguished association with the International Health Division of the Rockefeller Foundation is well known for his work on the hook-worm. At the early age of 26 he became professor of bacteriology and pathology at Kansas, and during this period he invented the apparatus with which his name will always be associated—the "Barber micro-manipulator." By the aid of this instrument bacteriologists are able to study the growth of individual minute organisms, and biologists to dissect individual cells, under far higher magnifications than were previously possible. In Dr. Barber's absence in Mexico the medal was received by his colleague, Professor Gunn, vice-president of the Rockefeller Foundation.

Professor EMILE BRUMPT was appointed professor of parasitology and natural history in the Faculty of Medicine of Paris in 1919. In the same year he undertook the heavy duties of Secretary-General of the Institute of Colonial Medicine of France, which he still carries out with energy, and in 1936 he was appointed director of the School of Malariology of the University of Paris. Professor Brumpt is the author of over 350 published papers. He founded the *Annals of Human and Comparative Parasitology*, a journal which he has directed from its inception, and his name is familiar to students in every country through his well-known textbook on parasitology, of which a fifth edition has recently appeared.

Professor WALTER SCOTT PATTON, who has worked in the Liverpool School for ten years, was for twenty years a member of the Indian Medical Service, and during that time he added much to our knowledge of the diseases of India. The value of his work was early recognized by his appointment as a specialist to investigate the aetiology of kala-azar and Oriental sore, and later by his promotion to the directorship of the King Institute of Preventive Medicine in Madras. In 1925 he was chosen by the Royal Society to be director of the Kala-azar Commission to Northern China, and two years later was appointed to the Dutton Memorial Chair of Entomology in the University of Liverpool. Professor Patton was unable to attend to receive the medal; it was received by his wife, who has added much to the interest and scientific value of his numerous publications by her exquisite drawings.

Professor WERNER SCHULEMANN, whose researches when director of the great German chemical firm of Bayer at Elberfeld have resulted in a discovery of such importance to tropical medicine that his name is known to all workers in this field. In 1924 he succeeded in synthesizing in the laboratory a chemical compound which not only acted on the malaria parasite but accomplished what quinine had failed to do, in that it destroyed the stage of the parasite which infects the mosquito. This outstanding achievement attracted

world-wide attention and gave a great impetus to the comparatively new science of chemotherapy, the full significance of which is only now beginning to be appreciated. Two years ago Professor Schulemann left the firm of Bayer to become professor of pharmacology at Bonn.

Lord Nuffield's Further Gift to the Wingfield-Morris Orthopaedic Hospital

Viscount Nuffield has shown a great interest in the development of orthopaedic services in Great Britain and throughout the Commonwealth. He has at heart the prevention of crippling and the cure of cripples, and has shown it in no uncertain way by giving various sums amounting in all to approximately £500,000 to the Mother Country and the Dominions of Australia, New Zealand, and South Africa for this purpose. In addition to this widespread munificence he has taken a special personal interest in the Wingfield-Morris Orthopaedic Hospital, Oxford; and it has been his purpose that this hospital should provide an example of all that can be done toward restoring activity to the disabled by surgery and by the natural healing powers of the sun and the open air. The Wingfield-Morris Hospital should, in his plan, be a working model, available to specialists and post-graduate students from all over the world. While the hospital draws its patients primarily from the three counties of Berkshire, Buckinghamshire, and Oxfordshire, and has a direct responsibility for the treatment of patients throughout this area, it is much more than a local hospital; and its committee feels bound to do all it can to make it an example fit to fulfil Lord Nuffield's aims and capable of demonstrating what is right in clinical work, in organization, and in design to all who visit it from far and near. Already, owing to the very great generosity of Viscount Nuffield, the main part of the hospital has been rebuilt, with every part planned exactly for its purpose. The wards, the surgical, physical treatment, and x-ray departments, the plaster room, the kitchen and laundry are all admirably designed and working faultlessly. The Wingfield-Morris Hospital is a voluntary hospital without endowment and, though many cases are partially paid for, it depends largely on voluntary subscriptions for its maintenance. The increasing pressure of the waiting list has demanded a gradually increasing number of beds; furthermore, the ever-rising standard of work, records, and research involves greater cost per bed. Recently the need for providing additional nurses' quarters, some twenty more beds, and for the replacement of obsolete hutment buildings had presented an acute need for capital expenditure. The additional quarters for nurses are, in the main, needed in order that their hours of duty may be reduced to the modern right and reasonable standards. The additional beds will also mean the need for a few more nurses. The hospital has, despite the increase of beds from 135 in 1932 to 180 in 1938, managed to reduce its net overdraft from nearly £5,000 in 1934 to less than £2,500 at the present time. But it has now been faced with a compelling need for a capital expenditure of £31,383, though with an overdraft rather than any means at its disposal. Once again Lord Nuffield has most generously stepped into the breach and, fully appreciating the necessity, given the hospital this sum.

Papworth Tuberculosis Settlement

In the annual report for 1937 of the Papworth Village Settlement the medical director, Sir Pendrill Varrier-Jones, stresses the psychological aspect of the treatment of tuberculous patients. For example, in the industrial departments, which are such a feature of the Settlement, no visible element of "charity" must be apparent, and every position, from that of general manager downward, must be open to a disabled man or woman. In order that the healing process may proceed without psychological embarrassment the patient must be free from the anxiety neurosis engendered by fear of unemployment. The

report points out that, by means of the Papworth scheme, patients who would otherwise have become permanent charges upon public funds or private charity are rendered wholly or partially self-supporting; their families are well protected against the disease, and the additional expense of treating new cases is thereby avoided: the happy and voluntary segregation in the Settlement prevents the spread of infection. "Every patient who becomes a settler at Papworth thus represents a twofold economy—a reduction in public expenditure and a reduction in public risk." Towards the end of the year the new home for tuberculous nurses was unofficially opened, and nurses from England, Scotland, Ireland, and Wales are now in residence. The report predicts that this home will shortly be filled to capacity, and the hope is expressed that similar institutions in other parts of the country may also be able to make provision for nurses suffering from tuberculosis.

Domiciliary Midwifery Service in London

A report has been made to the London County Council on the results of the first nine months' working of the Council's domiciliary midwifery arrangements under the Midwives Act, 1936. The number of patients attended during the period January 1 to September 30 was 8,137, of whom 2,465 were attended by the Council's midwives and 5,672 by the midwives of voluntary agencies included in the scheme. The number of midwives has been adequate, but in certain districts, owing to independent midwives surrendering their certificates, there have been heavy bookings, and the number of midwives employed by the Council has been increased from the forty-seven originally engaged to fifty-three. In view of the pressure on the accommodation in the maternity wards at the Council's hospitals, applicants for admission who are considered to be suitable for confinement at home are being invited to make use of the Council's domiciliary midwives. The section of the Midwives Act which prohibits the employment of unqualified persons for attendance as a nurse on maternity cases has been applied to London from November 1. These factors will have the effect of increasing still further the demand for the services of the Council's midwives.

The arrangements originally approved provide for a payment of £2 14s. for each patient attended. When a domiciliary midwife is taken away from a case by the Council, on account of the presence of infection, the further attendance is carried out by the district nursing association. If the complication is personal to the mother the association receives payment from the borough council under its maternity and child welfare powers, but if the midwife is removed because of other infection in the home the district nursing association, although providing nursing attendance for both mother and child, receives payment from the borough council only in respect of the child. The county council now proposes in such cases that a payment of £1 7s.—namely, half the usual fee—should be made.

It is stated that the arrangements are working with considerable success, thanks to the co-operation of the voluntary organizations and the borough councils, also to co-operation between the midwives themselves and the health visitors. Patients have availed themselves freely of the facilities provided by the borough councils, many of which have found it necessary to increase the number of sessions at their ante-natal clinics.

Remedial Exercises in General Medicine

The value of suitable exercises as an adjuvant to treatment is not perhaps fully recognized by all medical men. A demonstration of remedial treatments arranged by the London Branch of the Chartered Society of Massage and Medical Gymnastics at the Middlesex Hospital on December 16 gave some idea of the wide range of these methods outside the orthopaedic conditions in which their use is most familiar. Miss C. Sparger showed how ballet dancing

technique is applied to the correction of foot defects and the posture problems which arise from them and also give rise to them. The exercises are performed to gramophone music and are ingeniously devised to strengthen the muscles which are weakened as the result of deformity or misuse, and to stimulate the intrinsic muscles which maintain tone and cannot be contracted voluntarily. Miss M. Randall exhibited a range of exercises which, allied to simple teaching in the anatomy of parturition, greatly assist the normal processes of pregnancy and labour and enable the mother to co-operate with intelligent interest. Her stress on the value of ability to relax was repeated by Miss H. Angove in an entirely different connexion: that of the treatment of asthma. Patients must learn to relax before they can begin to learn the breathing exercises which are such a useful auxiliary to medical treatment and psychotherapy. They then exercise the walls of the chest and abdomen, and practise shaking movements on deep expiration. The whole course takes about three months, after which the patient is able to perform the exercises without supervision and is often already much improved. Mrs. Guthrie Smith's use of pulleys and slings is now widely known, especially in the treatment of the after-effects of poliomyelitis. She showed a film, and exercises by a sufferer from residual paralysis. As a patient in slings is released from the influence of gravitation and friction he can perform voluntary movements with muscles that are too weak to move under other conditions, but even the most vigorous exercises can be carried out in the sturdy tubular frame from which the slings are suspended. Miss G. E. Bristow demonstrated the use of short-wave current by spaced electrodes and by coil in the treatment of sinus infections, and Miss B. Copestake the preparation of Pistany mud packs for the treatment of sciatica and arthritis. The medical visitors expressed great interest in what they saw, and admitted that much of it was new to them. There is room for extension in the use of such measures in hospital, and even more so in private at the direction of the general practitioner.

IRELAND

Medical Research Council

The Medical Research Council of Eire has made the following awards, each for one year, for whole-time research: Mr. Patrick J. Boyle, M.Sc., investigation: (1) into the effect of the potassium ion on the kidney; and (2) to develop a micro-method for the estimation of glucose; the work to be carried out in the Department of Physiology, University College, Dublin, under the direction of Professor E. J. Conway. Mr. Thomas G. Brady, M.Sc., investigation into the occurrence of vegetable adenylic acid in plasma and tissues, the work to be carried out in the Department of Physiology, University College, Dublin, under the direction of Professor E. J. Conway. Dr. Owen T. D. Loughnan, investigation into the value of heparin in the treatment of established thrombosis, the work to be carried out under the direction of Professor J. M. O'Donovan, University College, Cork. Dr. Denis K. O'Donovan, investigation into the specific metabolic principle of the pituitary gland, the work to be carried out in the Department of Physiology, University College, Dublin, under the direction of Professor J. M. O'Connor. A grant has been made to Miss E. J. Power Steele, M.Sc., for part-time research into the degree of visual defect resulting from a deficiency in vitamin A, the work to be carried out at the Rotunda Hospital, the Physical Laboratory, Trinity College, Dublin, and other Dublin hospitals and schools, under the direction of Dr. Dockeray and Professor R. W. Ditchburn. The following grants-in-aid have also been made: Dr. Gerald FitzGerald, for one year for expenses in connexion with training in methods of neuro-pathological research in the

National Hospital for Nervous Diseases, Queen Square, London; Professor J. Brontë Gatenby and Miss Olive Aykroyd, B.A., for one year for an investigation of the secretory functions of the endometrium and uterine glands, the work to be carried out in the School of Zoology, Trinity College, Dublin; and Dr. E. F. McCarthy, for one year for an investigation of the oxygen affinities of human foetal and maternal haemoglobin, the work to be carried out in the Department of Physiology, University College, Cork. Original grants have been renewed for further periods, as follows: Mr. R. P. Cooke, M.Sc. (one year); Dr. Oliver-FitzGerald (one year); Dr. Ninian Falkiner (one year); Dr. Cecil Mushatt (nine months); Dr. T. C. J. O'Connell (six months).

Tuberculosis in Belfast

In his report for 1937 the chief tuberculosis officer of the City and County Borough of Belfast gives an interesting commentary on the sex incidence of tuberculous affections. He states that, while in 1915 the proportion of men to women suffering from tuberculosis was 100 to 150, the figure for 1937 was 100 to 83. Similarly with regard to mortality from tuberculosis in 1915, for every 100 male deaths there were 134 female; in 1937 the comparable number of female deaths was 97. It is further observed that, although in England there has been a fall in the incidence of mortality from tuberculosis among females of all ages, the death rate for young women of the age period 15-25 has risen during recent years. In Belfast, however, the mortality among young women has fallen, the rate per thousand showing a reduction of over 50 per cent., when comparing the quinquennium 1933-7 with that of 1912-16. "It is difficult to see what is the cause of the rise in the mortality from pulmonary tuberculosis in this age-period in England, or why we should not suffer from tuberculosis in the same age-period in Belfast. . . . any rate in the older industries—are better, hours of work shorter, and pay envelopes heavier. It is probable that the 'enjoyment' of additional leisure hours may be more exhausting than work; or again that conditions in the newer industries employing vast numbers of young women may not be so satisfactory as in the older."

Purdysburn Fever Hospital

Owing to the resignation of Dr. A. Gardner Robb from the post of medical superintendent of the Belfast Fever Hospitals the corporation has appointed Dr. F. F. Kane to be resident superintendent at the Purdysburn Fever Hospital, Belfast.

FRANCE

Tributes to Brown-Séquard

The recent unveiling of a commemorative tablet to Dr. C. E. Brown-Séquard at the University of Nice in connexion with the Congrès des Sociétés Savantes was made the occasion for several more or less biographical addresses by eminent men. One of them, Professor Acharé, classified the world's savants according as they were *savants dispersés* or *savants concentrés*. Brown-Séquard, he was sure, belonged to the former group, for not only was he always on the run, crossing the Atlantic more than threescore times, but he was also always without blinkers as a research worker. The fields in which he made his mark most clearly were those of experimental neurology and the internal secretions. With regard to the latter he was a pioneer indeed, and the experiments he performed on himself with testicular extracts made him incur the fate of most scientists who are before their time. But if he appeared then to be

somewhat lacking in mid-Victorian good taste, he was ultimately to be proclaimed as one of the founders of endocrinology.

Soundless Rest Cure in the Sahara

In a recent issue of *La Presse Medicale* Dr. Malachowsky has made himself the mouthpiece for a new scheme which is nothing less than a silence cure in the Sahara, recently traversed by him and found ideal for his purpose. For four weeks he has revelled in silent days and silent nights, undisturbed even by the rustling of a newspaper, so successful was he in escaping not only from the sounds but also from the news of the outer world. Other prospective benefits, which seem at first sight unconnected with an orthodox silence or rest cure, are the sterility of the desert sand, the high magnesium content of certain of the Sahara's waters, the comforts of the hotels, and the big-game shooting. The last-named in particular would hardly seem compatible with a silence cure unless the weapons employed are to be bows and arrows. Be this as it may, Dr. Malachowsky has announced that he is organizing a medical tour of the desert for a month at an inclusive charge of 12,500 francs.

Medical Obituary

The death is announced on November 7 of Dr. Roman Adelheim, professor of pathological anatomy at the University of Riga. Born in 1881, he did experimental work on the pancreas and, during the great war, he published in Russian a monograph on the pathological anatomy of poisoning by suffocating gases. Much of his more recent work was also concerned with the chemical side of modern warfare. He made important contributions during and after the war to the study of several infectious diseases, including small-pox, typhoid, typhus, and influenza. The death is also announced at the age of 55 of Dr. Durand Fardel, corresponding member of the French Academy of Medicine, and distinguished in the world of hydrology and thermal statistics. Another recent death is that of Professor Leenhardt of Montpellier. He was born in 1875, and was on his way, at the end of October, 1938, to Paris, to attend the Paediatric Congress, of which he was vice-president, when he died suddenly. He made important contributions to paediatrics.

Medical Lectures in Paris

The Association d'Enseignement Médical des Hôpitaux de Paris has organized for the scholastic year 1938-9 a series of Sunday lectures at the Paris Faculty of Medicine free of charge. The first lecture, given on November 20 by Dr. Bénard, dealt with the heart and sport. The subject of the second lecture was lipid nephrosis in the child. A series of twelve lectures and six practical demonstrations is being given in Paris this winter free of charge to all doctors, medical students, and persons interested in guidance in the choice of a trade, occupation, or profession. This course is given under the direction of Professor Tanon at the Faculty of Medicine, and is sponsored by the Institut National d'Orientation Professionnelle, whose leaders have foreseen that doctors taking part in this activity will need special training for it.

Events Postponed

The fiftieth anniversary of the inauguration of the Pasteur Institute will be celebrated on March 15, 1939, its celebration in the autumn of 1938 having been deferred on account of the critical state of the international situation. On December 3 the French League against Rheumatism gave the rheumatic demonstration which had originally been timed for October 8. A special feature of this meeting was the demonstration of patients operated upon for chronic arthritis and of a film showing the various stages of the operation performed.

Correspondence

Mechanical Respirators

SIR,—The "iron lungs" which Lord Nuffield is manufacturing and presenting to hospitals are made in accordance with the original design of Professor Drinker of Harvard University, but of wood instead of steel. Drinker himself had made a respirator of wood, but found steel to be better. In many Press notices of Lord Nuffield's gift the inventor appears to have been forgotten. It was the high incidence of infantile paralysis in the U.S.A. which led Professor Drinker, after much experimental work, to invent his respirator, and a large number of these are now in use in American hospitals. In 1930 Drinker brought an "iron lung" (as the Press called it) to England, and demonstrated its use to the medical profession. Sir Robert Davis purchased this particular apparatus and made arrangements with Professor Drinker for its manufacture. In accordance with medical custom no patent was taken out, but the apparatus was to be known as the Drinker respirator. The original machine was freely lent to several hospitals, and was the means of saving several lives, a notable case being that of the Stowe schoolboy, who recovered after treatment in this machine for many weeks at the Wingfield-Morris Orthopaedic Hospital. A cheaper model, of simplified construction, was, I understand, made and supplied to the London County Council in 1934 at the price of £97. Subsequently, as a result of the practical experience of L.C.C. medical officers, refinements and accessories were embodied, with increase in cost, but making for greater efficiency in operation and greater comfort for the patient. Lord Nuffield's model is similar to the simplified machine produced in 1930, but all the models are on Drinker's principle, and in justice to him should be referred to as Drinker respirators. While public welfare is paramount, and everyone appreciates the generosity of Lord Nuffield, credit is due and should be given to those who have made and perfected these respirators. It is doubtful whether a wooden structure will lastingly ensure the safety of the machine to meet emergencies, which very rarely occur. Another type of respirator in which rhythmic compression of the chest is used, invented by Sir William Bragg to meet the needs of a paralysed friend, has been perfected by Mr. R. W. Paul.—I am, etc.,

Bucks, Dec. 15.

LEONARD HILL.

SIR,—A few months ago, when I had occasion to place my first case of acute poliomyelitis with respiratory paralysis in a box respirator, I found the procedure of drawing the child's head through the opening in the rubber diaphragm a difficult task and a most uncomfortable ordeal for the patient. Subsequently, I made a five-inch split in the rubber diaphragm towards the periphery, which split is opened and closed by means of a zip fastener sewn on to thin leather stuck to the rubber. I communicated the idea to Mr. Both, and such rubber diaphragms, complete with zip fasteners, are now supplied by Messrs. D. and J. Fowler, 215-218, Mansion House Chambers, Queen Victoria Street, E.C.4, or the ordinary rubber diaphragm can be easily converted at but little cost and labour.

I feel that this simple method, whereby a patient can be placed in and taken out of the box respirator with considerable ease, should be universally known to all users of box respirators, whether of the "Drinker" or "Both" type. As box respirators have been but little used in this country

until recently, and there appear to be no detailed instructions available regarding practical points in nursing, I venture to stress the importance of frequent postural changes, as in the treatment of enteric fever, owing to the great liability of poliomyelitis cases with respiratory embarrassment to develop hypostatic congestion and pneumonia.—I am, etc.,

Cardiff, Dec. 19. G. EMRYS HARRIES, M.B., B.S., D.P.H.
Medical Superintendent, City Isolation Hospital.

Cardiazol for Schizophrenia

SIR,—With regard to the annotation on the dangers of cardiazol treatment in the *Journal* of December 17 (p. 1267), there is a source of damage other than the asserted frequency of fractures or dislocations, or the impairment of memory. Fractures are rare if adequate precautions are taken. Obviously, if patients who have not had any exercise for some time, or are middle-aged, are subjected to the treatment without due preparation, fractures will be frequent. Also, dislocations of the shoulder or jaw are in my experience uncommon; in the 430 convulsions which I induced during this year dislocation of the jaw happened twice and dislocation of the shoulder not at all; there were no fractures. It is true that quite a number of patients complain of their memory while undergoing treatment, but with my patients this has been temporary, and the memory recovers soon after completion of the treatment.

While satisfied that convulsion treatment has a wide therapeutic range and promotes recovery in many cases, I see a serious danger in overestimating the spectacular effects which often occur soon after commencing the treatment, for these may be quite misleading as to the ultimate result of the treatment. With convulsion therapy it is not difficult to obtain such effects; the difficulty is to knit them together into lasting improvement. This should be better known than it is at present, or the very advantages of convulsion therapy will lead the enthusiastic physician, and with him the public, to believe that mental disease, whatever its type or duration, can be cured by a few convulsions.—I am, etc.,

London, N.6, Dec. 19.

H. PULLAR STRECKER.

Oxygen in Treatment of Sciatica

SIR,—A discussion on sciatica and its treatment at the Annual Meeting at Plymouth last July was opened by Dr. Wilfred Harris (*Journal*, December 17, p. 1245). It is rather surprising that a simple, painless, and in many cases extraordinarily successful method—the subcutaneous injection of oxygen—which may give immediate relief, and even effect a complete cure in both acute and chronic cases of sciatica, was not even mentioned. This treatment was described by Dr. J. P. Martin in volume iii of *Modern Technique in Treatment*, published by the *Lancet* in 1927. The method is especially useful in the treatment of those cases of sciatica which are most commonly met with and which are so difficult to cure—the rheumatic or toxic form, in which there is interstitial inflammation of the nerve with perineuritis. In these cases the subcutaneous injection of oxygen may give immediate relief, which may be permanent. Dr. Martin says: "This method of treatment is suitable in acute and subacute cases, and though it may be somewhat uncertain its extreme simplicity makes it always worth trying."

Drs. James Collier and W. J. Adie, also of Queen's Square Hospital, who were responsible for the section on diseases of the nervous system in Price's *Textbook of the*

Practice of Medicine, used these words: "Massive injection of oxygen into the region of the affected nerve is a simple and harmless method which gives no pain and often brings most conspicuous relief." My own experience of this treatment has been comparatively small, but in the cases I have seen the effect has been very striking.

A man who had been completely incapacitated by sciatica and confined to bed for several months had obtained little if any benefit from treatment, with the exception of saline injection into the nerve, from which he obtained some relief; but after the injection of oxygen he was able to walk without pain and resume his work. Another case, a member of my own family, had been incapacitated by sciatica for about five months and had suffered many things of many physicians, including epidural injections into the sacral canal, which, though very painful, gave little if any relief. She was completely cured after two or three subcutaneous injections of oxygen. I found injection of oxygen equally effective at an early stage of the disease. A middle-aged woman who had been confined to her bed for a week with acute sciatica was also completely cured after three injections of oxygen.

The method which I have employed is to connect by sterilized rubber tubing a cylinder of oxygen with fine adjustment to a sterile Record needle about $\frac{1}{2}$ mm. in diameter and 2 inches long, via a bottle containing warm water. When the gas is bubbling gently through the bottle the needle is introduced into the subcutaneous tissue at the back of the thigh, in the line of the sciatic nerve, just below the gluteal fold. It may be introduced for a distance of about an inch or even more, care being taken that it does not penetrate muscle but remains confined to the cellular tissue, so that the oxygen may penetrate to the region of the sciatic nerve between the hamstring muscles. The subcutaneous tissue of the thigh will quickly become emphysematous and "ballooned" with gas; when the skin is judged to be sufficiently tense the needle may be removed. The injection will cause no pain unless the gas is being injected into a muscle, which will be extremely painful and will be unaccompanied by subcutaneous oedema and emphysema. The emphysema subsides fairly soon and will have quite disappeared in forty-eight hours, when another injection should be made lower down in the middle line of the thigh over the sciatic nerve. If necessary a third injection may be given just above the popliteal space. If care is taken to inject into the subcutaneous tissues only complete relief of pain may be expected.

Recently a very simple and handy apparatus for this treatment has been devised by Sparklets, Ltd., by which 1 litre of oxygen can be introduced on each occasion. The apparatus fits into a small box, which may be easily carried in a doctor's bag. Subcutaneous injection of oxygen might also be used in a similar way for the treatment of brachial neuritis.—I am, etc.,

Worthing, December 17.

HERBERT H. BROWN.

Decline of Breast-feeding

SIR,—In my experience of infant welfare centres I have seen a large number of cases similar to those described by Dr. H. W. Pooler in your issue of December 3 (p. 1176) in which the breast milk diminished in quantity during the first month after confinement, directly the mother began her daily domestic duties in the home. I think the cause of this condition is psychological. While lying in bed the mother concentrates on breast-feeding, whereas when she is doing her domestic duties she has to think of other things as well. The change of environment is really responsible for the temporary inhibition of the milk supply; as time goes on she gets used to her dual functions and her nervous system adjusts itself; the temporary inhibition is then removed and full lactation is resumed. The duty of those who give advice at the welfare centres is to tide over this period of adjustment

so that the child can continue breast-feeding. The rich mother is not bothered nearly so often with this diminution of milk when she resumes household duties. She of course lies in bed very often for three weeks and so allows time for full lactation to be established.

Lately a method has been started of preserving breast milk: a full description of its clinical application was published in the *American Journal of Diseases of Children*, February, 1938 (p. 249). Briefly, it consists in collecting breast milk in maternity institutions and pasteurizing it. It was found that 150° F. (the normal pasteurization temperature) failed to prevent the appearance of pathogenic organisms in the milk within two weeks; also boiling the milk in an open pan for thirty minutes on three successive days was not satisfactory. Broadhurst and Duncan in 1933 pointed out that breast milk heated to 175° F. for thirty minutes on three successive days would remain sterile indefinitely when refrigerated properly. At the end of two years the milk was sterile and the chemical composition was similar to fresh breast milk. The Infants Hospital, Vincent Square, has carried out this scheme of preserving breast milk with similar results to those in America; they found the milk remained sterile and that its chemical composition resembled in every way fresh breast milk. I hear a similar scheme is being adopted at Queen Charlotte's Hospital. I believe if this scheme is universally adopted there will be some chance of reducing our high neo-natal mortality. I see no reason why in the near future the general practitioner should not be able to obtain breast milk for some of his feeble infants and those suffering from digestive disorder who cannot thrive on cow's milk in any form.—I am, etc.,

London, W.8, Dec. 12.

RONALD CARTER.

SIR,—Dr. Ronald Carter, in the *Journal* of December 10 (p. 1229), mentions the experience in India of Dr. Ruth Young, who took part in the discussion on this subject at the last Annual Meeting. Being an Indian born and bred, I can testify from personal experience and knowledge of the working women of India, who live on practically starvation wages, that the amount and quality of food taken bear little relation to the secretion and quantity of breast milk. Their main diet consists of *bajri* (a kind of rye) bread and *chutni*, made of greens, spices, and coconut. In the higher social strata the Indian women form two groups: those sophisticated by Western culture and those not so sophisticated. Among the latter the secretion of breast milk does not differ from that in the working-class women; but among the sophisticated women, and particularly the Parsees of Bombay, the secretion of milk shows the same variations as in the corresponding types of Western women. It is the custom among most Parsees, especially when confinement takes place at home, to make young mothers partake of *soonth*, a delicious though rather heavy preparation of ginger, nuts, flour, sugar, and spices, during the period of confinement (this used to be forty days but is now usually ten to fifteen days). The *soonth* acts as a galactagogue to a certain extent but not unless the condition mentioned in the following paragraph prevails.

To my mind the main reason for the decline of breast-feeding is psychological. The woman with true motherly instincts always secretes the necessary amount of milk, and more to spare, for her baby. But the one who regards motherhood as a matter of sufferance, or who considers herself deprived of her petty privileges of social and domestic engagements and outings, and who thinks these disadvantages outweigh the happiness derived from the presence of the baby in her arms or by her side, would

hardly supply the psychological stimulus so essential for the secretion. Quantity and quality of food, the presence of vitamins therein, social and domestic comfort, requisite exercise, massage, etc., may act as secondary or supplementary stimuli but not the essential one. There may be exceptions, but, as usual, they do not constitute the rule.—I am, etc.,

London, E.14, Dec. 16.

ARDESHIR D. JILLA.

SIR,—I have read with interest Dr. J. C. Spence's paper in the *Journal* of October 8 (p. 729) on the decline of breast-feeding and the subsequent correspondence. It is agreed, I think, that the breast milk often tends to diminish at the end of the first fortnight, when the mother returns to her many household duties.

Recently I came across a statement—I cannot find the reference now—made, I think, by the professor of gynaecology and obstetrics at either Edinburgh or Glasgow, that an injection of 2 c.cm. of a concentrated liver extract (for example, anahaemin, pernaemon forte, or similar preparation) would restore lactation in such cases. Knowing the difficulty one always has in dealing with these patients, and as an injection of liver extract could in any case only be of benefit to the mother, I have tried this remedy on two occasions: (1) for a woman whose milk failed two days after returning from the maternity hospital, and (2) for a woman whose milk failed when the baby was nearly 3 months old. On both occasions a full supply of breast milk was obtainable in two to three days, and was maintained, to the gratification of both the mother and myself. The success of this treatment suggests that failure of lactation may in many cases be due to anaemia, and/or to the deficiency of other essential factors, as the result of the pregnancy.

I should be interested to know of others who have tried this remedy, and also to whom I am indebted for the original idea.—I am, etc.,

Napier, New Zealand, Nov. 29.

A. C. B. BIGGS.

A Voluntary National Register of Land for War-time

SIR,—Some three years ago I had an opportunity of seeing the new general hospital at Malacca. This imposing structure, comprising several blocks five stories high, contains installations of the most modern description; its wards, operating theatres, and equipment are considered second to none in the East. This type of hospital offers many advantages from the point of view of efficiency and easy administration in time of peace.

During the last three years it has become evident that air warfare is developing according to ideas which no longer regard military establishments as the only proper objectives. If Malaya becomes involved in war this magnificent building, on elevated ground and a conspicuous landmark for miles, will prove a tempting and easy target for the enemy. To meet this danger two policies are available. The first is to guard the hospital from attack by anti-aircraft defensive measures; the difficulties of this are likely to prove insurmountable. The second is to remove the patients immediately to other and safer quarters. Fortunately rapid progress has been made during recent years in the methods of construction and erection of temporary hospital buildings, and in Malaya there should not be any difficulty in obtaining sufficient land in positions giving a degree of concealment and security from air attack.

But a similar danger arises in this country wherever great hospitals exist, especially in or near any town liable

to be bombed. Unless there is an adequate preventive method against air raids or there is bomb-proofed hospital accommodation locally, the rapid evacuation of patients to semi-permanent quarters remote from the town is unavoidable.

From recent disclosures it is evident that no such preventive method or safe accommodation yet exists. Arrangements should therefore be made beforehand to acquire the use of suitable sites at a safe distance, from these populous centres. For maximum safety the war hospitals will no doubt have to be erected in one-story blocks, as widely separated from each other as is reasonably possible. This plan, analogous to that employed for many explosive factories, will minimize the casualties from high-explosive or incendiary bombs. Presumably the methods applicable for ensuring the safety of hospital patients will apply also to other classes, such as school children and residents in various institutions. Any considerable number of persons housed in one large building in an area exposed to the danger of air attack will require to be dispersed at once.

The public would be much reassured about the danger from bombing in time of war if they knew that the various hospital and other authorities had secured beforehand an option on all the land necessary for these war-time buildings. A very large area of land will be required for such purposes, and one simple method of ensuring immediate access to it on the outbreak of war would be the formation now of a voluntary national register of all suitable lands. If necessity arose, the register could at once be given a compulsory form.—I am, etc.,

Liverpool, Dec. 21.

D. B. BLACKLOCK.

Control of Small-pox in India

SIR,—I feel I must reply further to Dr. C. Killick Millard's letter (December 10, p. 1228). The mortality figures do not in any way disprove the value of vaccination or suggest that it has failed to protect the community. The proportion of persons vaccinated in the whole population is small, and vaccination cannot be talked of as having been "pushed" as far as ever was practicable; the statistics cannot be relied on and the number of sears is generally inadequate. In pre-vaccination days 90 per cent. of deaths were at ages below 5 years. In any community the deaths from small-pox were limited to the unvaccinated, and, apart from vaccinated units being factors in the protection of a community, the fact that vaccination has raised the age incidence of mortality shows its general protective value. I cannot agree that "medical authorities . . . for years" have been educating the people as to vaccination in India. A few leaflets and lectures in some cities can hardly be called "educating the people." As to variolation, Dr. Millard need not go so far back as the practice in the East. We had it in England, when it spread the disease, had disastrous effects, and disfigured many; it still remains a penal offence by the Act of 1840 which stopped it. There is no evidence adduced that variola would protect against the major disease any more than vaccination, nor that it would not cause an outbreak of the major variety. Would Dr. Millard allow himself to be variolated from the pustules of some unknown arm? If not, why should he advocate it for Indians? It would be difficult to persuade the various castes that the variolation was only from someone in their caste. Even then, with the existence of many blood diseases there is the danger of transmission of some of these.

India is ruled by civil authorities. Medical officers would have to persuade the various civil surgeons, sanitary commissioners, deputy commissioners, commissioners, and the Lieutenant-Governor before the method could be sanctioned. It might take ten years of cross-arguments before a decision would be arrived at. Presuming it was, it would be still more difficult to get it passed through an enlightened Indian municipality. I fought four years for a small-pox hospital, and though all the above officials supported me the municipality did not see the need. Medical men in India are not to be blamed; they are generally overworked if in any official position, and general practitioners work under the silly competitive system (as in England). In rural areas things are more difficult; there are no hospitals except such as may be provided among a community of industrial concerns. Isolation for small-pox is impracticable except by a too-late temporary hut.

You cannot try these experiments in India so easily as Dr. Millard thinks. The people, however, will be led by their leaders, and the best hope lies in educating these leaders. I am just as anxious as Dr. Millard to see small-pox reduced in India. If he could give something more than theory—some definite proof that such a variolation would stamp out both varieties of the disease—and could then persuade the medical officers of health, etc., in India that it would be so, then he would be a benefactor to India. I wish him luck.—I am, etc.,

Ilford, Dec. 13.

A. G. NEWELL, M.D., D.P.H.

Social Pathology

SIR,—Perhaps you will allow me to offer your readers a somewhat fresh view of the fall in national population, which, most unreasonably, has come to be looked on as inevitable. A journal which at once leads the great medical profession and responds to its growth in thought will not, I feel sure, refuse a hearing to any who firmly believe national decay can be avoided. It is, no doubt, likely that moral, religious, and conventional prejudice will stand in the way of a fundamental reorganization of the social rules inhibiting sexual fertility. But if anything, however drastic, can be done to stay the approved processes which are destroying this nation, as they destroyed other nations throughout the ages, social morality and religious ordinances should lose all authority. I shall say a little of the fact that at present this nation, misled by a socially harmful philanthropy, spends millions and immense energy to preserve those who should be allowed to die. The temporary and costly salvation of the unfit and insane is lamentable enough, since even the more healthy elderly and aged use up energy which might help the young to live and grow. It is, then, true that we should recognize that overlong survival is a sign of racial and social degeneration, but what is far more serious in our social system is the fact that possible and necessary birth is actually prevented. I do not refer to birth control, a purely secondary phenomenon with which I should not venture to trouble a philosophical journal. A very little time ago the most prominent population problem in the world of Malthus and Darwin was over-breeding. We can fear this no longer. But is what we do fear a natural world process? Racial death may matter little to philosophers, but, fortunately, they matter less to the world. For how comes it that neither they nor statesmen nor physicians have solved this simple problem? During the last few years I have noted, not wholly without such a measure of intellectual pity as a social Pyrrhonist may reserve for himself and his friends, the way in which many

of the best-regarded intellects of Europe have struggled vainly with it, without so much as touching on basal physiology. Are we then to understand that neither statesmen nor physicians, to say nothing of moralists, are able to grasp the elementary proposition that the one and only way to fertility is fertilization?

Women in the mass are the female generative organ of the social organism, and yet everything is done by the interposition of moral, religious, and economic obstacles to render this organ barren during the period of early reproduction. It is well known that the proper fertile age of women runs roughly from 14 to 28. Yet what are our social practices? We forbid intercourse by law for two years of that period. It is even proposed to add two more barren legal years. An illegitimate child is doubly a social crime, not a racial gift. Early marriage is too often discouraged by elderly, jealous, and possessive relatives, who wish to keep their children as servants, not to say slaves. This evil factor tends to increase with the noted and lamentable increase of the old. As regards the upper and middle classes, which are most in danger of extinction, there is, however, little need for direct parental discouragement, as economic conditions tend to make these classes defer marriage till the age of fertility is practically over. By this time the selfish pleasures of a dying social system have taught young women to avoid the residual fertility their instincts earlier made them eager to seek. It should be as obvious to the medical profession as it is to nurses and to schoolmistresses that girls should begin to produce offspring about the time they begin at last to neglect their dolls, even though they feel the vain and empty want of them. This very plain doctrine, which declares the whole truth as to race failure, will no doubt be damned as conducing to immorality and even to direct State aid of illegitimacy. This I shall not attempt here to discuss. In the end it must be left to those most deeply concerned to settle whether racial death or the collapse of an antiquated moral system is to be preferred. This decision must clearly lie in the hands of those who suffer most from ethical doctrines which doom the race to death. We may well inquire whether these doctrines have not already broken down in a rebellious self-indulgence which remains barren when with a new morality, so sorely needed, the nation might renew its growth and power.—I am, etc.,

London, N.W.3, Dec. 19.

MORLEY ROBERTS.

A Museum of Practical Radiology

SIR.—In his admirable contribution to the debate in the House of Commons Sir Francis Fremantle deftly placed two fingers on the weakest points of the Cancer Bill. In the first place he pointed out that radium was not the only cure but ranked equal with surgery and deep x rays. In the second place he pleaded for early diagnosis, and this depended on the acumen of the general practitioner who first saw the case. In the diagnosis of internal cancer, especially of the stomach and colon (the commonest sites), x rays stand unrivalled for early diagnosis; and where can the practitioner learn what are the appearances and how can radiology help him in his daily round? The radiologists have not even a museum for their own training, let alone one for the education of the general practitioner. There are few lectures for those not taking up the specialty as a full-time occupation. The only collection of prints available is at the Wellcome Museum, Euston Road, where it is in an ideal setting, being accompanied by photographs, specimens, and microscopical slides; but this does not profess to be an x-ray

museum, and Dr. Daukes has told me that he has difficulty in obtaining radiographs even there.

Ever since 1929, and in each edition of my *Descriptive Atlas of Radiographs*, I have been urging the need for an institution worthy of British radiology. Unlike radium and deep x-ray therapy, which are hardly out of their infancy, the diagnostic side of radiology has almost passed the stage of an art and is a science in the hands of the capable. The once familiar laparotomy is rarely performed in the larger cities in America and on the Continent; the condition is diagnosed previously by x rays, and not only this but fruitless operations on the inoperable can be avoided, with relief to surgeon and patient.

The best location for such an institution or clinic is a matter for consideration. In London and the large provincial towns it would interfere with existing bodies; the mixture of graduates and undergraduates is never satisfactory. After many years of thought I have come to the conclusion that it would be best to start *de novo* in some small provincial town where there would be no outside interference, no counter-attractions, and where students (I refer to graduates attending) could "sleep" in the subject for their week's intensive course. Such a place would be "alive," since students could see patients actually being radiographed and examined; merely a collection of prints, specimens, notes, etc., would tend to make the place "dead."

The late Dr. Stanley Melville once told me that he did not want radiology popularized, because that would lead to the mushroom growth of practitioner-radiologists, which would be bad for the science. Anyone who has had the working of a busy practice knows that the last thing he wants is to be bothered with the developing, etc., of an x-ray plant, but he would like to know how radiology would help him in his daily task, particularly in confirming the early symptoms of disease. The idea of a small town as a site may not appeal to all at first. But what was Rochester, Minnesota, but a small village until the Mayo Clinic transformed it into a town of hospitals and hotels? Into such a foundation it would be possible to import an occasional wizard of the science from abroad, with obvious advantages to British radiology.

I consider Sir Francis Fremantle has made a notable step in our search for knowledge in the cancer campaign.—I am, etc.,

London, W.1, Dec. 19. A. P. BERTWISTLE, F.R.C.S.Ed.

Adrenaline Treatment of Asthma

SIR.—To show how little the connexion between asthma and nasal polypi in aspirin-sensitive patients is appreciated may I mention two cases.

The first was an aspirin-sensitive patient who consulted me and said that he had been slightly troubled by asthma and was sent to a rhinologist, who removed a number of nasal polypi. Immediately his asthma became severe and continuous, necessitating an injection of adrenaline every three hours. The patient returned to the rhinologist, who informed him that his business had been to remove the polypi and that he must now consult a physician about his asthma.

I succeeded in stopping long-standing asthma in the second case, a man with nasal polypi who was aspirin-sensitive, and for six years he remained absolutely free. He then consulted me again because his nasal obstruction made him snore, and as he had been free from asthma for so long he thought there would be no risk in having his polypi removed. I persuaded him that the nasal obstruction was the lesser of the two evils, and he was content. Eighteen months later he came to see me again because he had consulted an aurist who discovered the polypi and said they must be removed. The polypi were removed, with the result that the asthma returned the same day

orders granting leave of absence were all in the same form. They were headed "Order for discharge of patient" and read:

"We, the undersigned, being members of the committee of the hospital, do hereby certify that the patient named above, who is now under treatment in the hospital, is fit to be discharged, and that the committee of the hospital is of the opinion that the patient should be discharged."

The medical officer certified on the same form that the patient was fit for "provisional discharge." The form was presented in February, 1938. In February, 1938, the patient was discharged. During the five years she was absent for varying periods beginning every Christmas. She was during the whole time incurably of unsound mind. Her advisers admitted this at an early stage. But contended that she had not been continuously under care and treatment for five years. Simply stated, the question for the decision of the court was whether or not she was under care and treatment while living with her sister.

The Solicitor-General agreed that the form or the order could not be justified, for there was no such thing in law as a provisional discharge. He argued, however, that the visitors had intended to allow the patient to be absent on trial in accordance with Section 55 of the Lunacy Act, 1890. This section permits any two visitors, with the advice in writing of the medical officer, to allow a patient to be absent on trial as long as they think fit, and if a patient absent on trial does not return when his leave is up, and the visitors or the manager of the hospital do not receive a medical certificate that he need no longer be detained as a person of unsound mind, he may be retained within fourteen days as though he had escaped. The Solicitor-General maintained that detention did not necessarily mean physical detention or being locked up. The Board of Control held the view, he said, that Section 55 might properly be used on behalf of patients to whom they reacted to ordinary life. "On trial" does not refer to trial whether a patient has recovered; indeed, in this case it was common ground that the patient was still of unsound mind. The question to be tried was whether the environment of a holiday camp or some other place is suitable for the patient. He went on to argue that if a discharge takes place, whether the patient is cured or not, then control is exercised by the manager under the regulations of the hospital for three nights or four days; absence on trial for a fixed period; and absence on trial for an indefinite period. If detention in fact is required, he said, these varieties of absence would require separate consideration. He was not prepared to hold that detention would be interrupted by routine outings in the daytime, and he assumed, without deciding, that an occasional absence for three nights or four days would not interrupt the detention, on the principle of *de minimis non curat lex*. Even so, he thought, such absences might be so frequent that it would be impossible to disregard the accumulation of days of freedom during the five-year period. It might be impossible to draw a line to fit all cases, but he thought that, if detention in fact was required, absence on trial for prolonged and indefinite periods must be on the wrong side of any reasonable line.

The President referred to the Divorce (Scotland) Act, 1938, but did not lay much stress on the comparison of its wording with that of the English Act. On the wording of the English Act he could not hold that liability to be detained if a reception order was called out of abeyance was the same thing as actual detention under an order which was being enforced. So far as concerned the medical superintendent, there was no necessity for the wife to be detained at all or for her to return to the asylum, except the convenience of her sister. By Section 55(8), when a patient is on trial, any medical man can send a certificate to the visitors certifying that detention is no longer necessary. The certificate does not necessarily mean that the patient has recovered. When it is sent, the reception order ceases to be enforced. The President remarked that it seemed absurd, in a case like this, that the question whether a patient who is allowed more or less indefinite leave of absence on trial is "continuously under care and treatment" may depend on whether or not some

Mr. H. W. Barnard, appearing for the wife, said that the absences under an order having no legal force were equivalent to an escape; or else the order operated as a discharge and killed the reception order. Alternatively, if the reception order was alive the detention had been interrupted and the patient had not been under care and treatment continuously for five years. He urged that the word "detained" must be strictly construed.

The President, in his judgment, remarked that the schedules of forms in the Lunacy Act, 1890, do not set out a form for discharge or for any kind of temporary release. Moreover, the Act, he said, does not recognize such a thing as a provisional discharge. It recognizes several ways in which a patient may in fact be at large though the reception order remains in force. He pointed to Section 85, which provides that an escaped patient may be retained within fourteen days by the manager of the asylum in which "he was detained"—the implication being that after he escaped he was no longer under detention; and to Section 57, which provides for the

The Judgment

Turning to the form of the order under which the wife was released, the President said that it was a composite form which could be, and later was, adapted to an absolute discharge. The word "provisional" had been inserted in writing in a blank space. There was no provision in the Act for varying asylum patients "on holiday"—the phrase in current use in relation to private patients released for the benefit of their health. There was no provision in the order that Mrs. Shipman's sister would be "responsible" for her—a word used in the entry in the hospital book relating to the absence. He accepted the argument of the Solicitor-General that she had been "absent on trial" within the meaning of the Act, and that it had been lawful for the authorities to receive her back although no further order had been made and she had not relapsed. He therefore held that the reception order had remained in force at all material times, but he hoped that the case would result in the local authorities considering putting their house in order, for the argument had shown that they ran a considerable risk in matters unconnected with divorce through the confusion which prevailed in their exercise of their powers.

Assuming that the reception order was in force at all material times, he had next to consider whether the wife was continuously detained under it. According to the Solicitor-General she was to be considered as "detained" if a reception order was continuously in force under which she was liable at any time to be received and detained in the hospital, whether she was actually detained or not. This solution would be simple, and would relieve the court of all the difficulties which would arise if detention must be proved. There are, the President observed, four varieties of permissive absence: any temporary outing, unattended, during the time of day when patients are not locked in; leave of absence granted by the manager under the regulations of the hospital for three nights or four days; absence on trial for a fixed period; and absence on trial for an indefinite period. If detention in fact is required, he said, these varieties of absence would require separate consideration. He was not prepared to hold that detention would be interrupted by routine outings in the daytime, and he assumed, without deciding, that an occasional absence for three nights or four days would not interrupt the detention, on the principle of *de minimis non curat lex*. Even so, he thought, such absences might be so frequent that it would be impossible to disregard the accumulation of days of freedom during the five-year period. It might be impossible to draw a line to fit all cases, but he thought that, if detention in fact was required, absence on trial for prolonged and indefinite periods must be on the wrong side of any reasonable line.

The President referred to the Divorce (Scotland) Act, 1938, but did not lay much stress on the comparison of its wording with that of the English Act. On the wording of the English Act he could not hold that liability to be detained if a reception order was called out of abeyance was the same thing as actual detention under an order which was being enforced. So far as concerned the medical superintendent, there was no necessity for the wife to be detained at all or for her to return to the asylum, except the convenience of her sister. By Section 55(8), when a patient is on trial, any medical man can send a certificate to the visitors certifying that detention is no longer necessary. The certificate does not necessarily mean that the patient has recovered. When it is sent, the reception order ceases to be enforced. The President remarked that it seemed absurd, in a case like this, that the question whether a patient who is allowed more or less indefinite leave of absence on trial is "continuously under care and treatment" may depend on whether or not some

Obituary

E. L. FOX, M.D.

Dr. Edward Lawrence Fox, who died on December 1 at the age of 79, was a member of an old Plymouth family. He was educated at Cambridge University, where he proceeded to his M.D. degree in 1890, and at St. Bartholomew's Hospital. He became M.R.C.P. in 1891, and was appointed physician to the hospital that is now the Prince of Wales's Hospital, Plymouth, in 1894. He reached the position of senior physician before resigning under the age limit in 1926. He was also consulting physician to the Royal Eye Infirmary and to the Plymouth Public Dispensary. Dr. Fox was a pioneer in the use of thyroid extract for the treatment of myxoedema, and a paper from his pen on this subject was published in this *Journal* in 1892. He was, however, better known to his colleagues and the public for his work on functional nervous diseases. During the war, in which he held the rank of lieutenant-colonel, R.A.M.C., he had charge of the neurological cases in the war hospitals at Plymouth and in the district.

He was a man of very strong character and held decided opinions, in connexion with which his attitude was uncompromising, but he was held in high esteem by his colleagues and the people of Plymouth on account of his integrity, his friendship and care for his poorer patients, and for his private generosity, which was never advertised. Shortly after the end of the war he married, and lived a life of the greatest happiness with one who shared his many interests to the full. His private life was one of great activity, for he was devoted to the creation of beautiful gardens, and, in addition to the one at his country home at Bantnam, he constructed several in selected situations on land belonging to his friends. His main interest in these was the cultivation of rare alpine plants and heaths. He was also a keen fisherman, and gave a great deal of attention to the breeding of trout. By his death Plymouth has suffered a severe loss, for one who continued his professional interests, his hobbies, and his philanthropic works to the time of his last illness will be very difficult to replace.

Dr. Fox had been a member of the British Medical Association for forty-seven years, and was a member of the Central Council of the Association from 1901 to 1907. He also held office as vice-president of the Section of Medicine when the Association held its Annual Meeting at Exeter in 1907.

Dr. Harry Finley of West Malvern died on December 12 at the age of 70. He was the son of the late Henry Thomas Edward Finley of Wimborne Minster, Dorset, and was educated at the Grammar School. From there he went to University College, London, taking his M.B. in 1892 and his M.D. London in the following year. He held resident posts at University College Hospital, London, and at the Cumberland Infirmary, Carlisle. He then spent some years in temporary appointments in various parts of the county, ranging from Devonshire to Midlothian, before settling at West Malvern in 1899. He was carrying on his regular duties up to the evening of November 14, when he was suddenly taken seriously ill in his own home. For many years he was a valued member of the staff of the Malvern Hospital. Among his appointments were consulting surgeon of the Malvern Hospital, medical officer

"We the undersigned being two of the visiting justices of private asylums for Kent hereby sanction leave of absence from Mallings Place to X on probation for the period of twenty-eight days; but this sanction is revocable by us at any time during that period; provided that the medical officer shall at any time before the expiration of the said period have power to take back the said patient into the licensed house if his mental condition requires it."

Quite incidentally the case has shown that the practice of at least one mental hospital in granting leave of absence is not in accordance with the law. The President referred to a form of order for absence which was set out in the opinion of Viscount Cave (then Lord Chancellor) in the report of Harnett's case (at p. 676), and which, he said, would afford an excellent model for the guidance of the mental hospital concerned. It was said to have been approved by the Law Officers of the Crown of that day.

This decision, therefore, lays down that when a patient is absent on leave he is not under care and treatment, because he is not "detained." If Parliament intended in 1937 that absence from the mental home should be an indispensable part of this ground for divorce, as well as the incurable insanity, then the decision is in accordance with its intention, and the only amendment needed in the Act is one which will more precisely define the meaning of "care and treatment." In view of the wording of the 1937 Act—"it is incurably of unsound mind and has been continuously under care and treatment for a period of at least five years"—it is difficult to see how the Legislature could have meant to grant a divorce merely for incurable insanity in a patient who was harmless enough, as this patient was, to be allowed out for long periods. One implication of the decision seems to be, however, that in order effectually to bar a petition for divorce on the ground of insanity it is only necessary for the patient to obtain a long leave of absence. If during that leave the patient or his advisers can find a medical practitioner who will certify that he need not be further detained, he will make doubly sure, for the reception order itself will be killed.

Implications of the Decision

doctor sends the visitors a certificate. The five years may include a period of treatment as a voluntary patient, provided it follows without any interval a period of detention under certificate. In the President's opinion this strictly limited reference to treatment as a voluntary patient serves rather to mark the contrast between the words "treatment" and "detention." If Parliament had intended, he said, to take as the test any kind of care and treatment—voluntary, temporary, or under certificate—it could quite easily have said so. As Parliament had not chosen to say so, it was not for the court to legislate. Moreover, wrongful detention as a lunatic gave rise to an action for false imprisonment, and the President could not see how an ex-patient could allege false imprisonment in respect of a period when he was, in fact, at large by permission. In *Harnett v. Bond* a private patient was ordered twenty-eight days' absence on trial; during that period he came to Dr. Bond's office, and Dr. Bond, considering that he was in a very excited state, sent for the medical officer of his asylum, who, according to the proviso in the leave of absence order, could take him back, if his mental condition required it. Dr. Bond, however, forcibly detained the patient until the medical officer arrived, and admitted that he had no legal justification for doing so. These facts seemed to the President inconsistent with the notion that, while that patient was absent under the leave of absence order, he was detained in pursuance of the reception order. For these reasons the President held that the required ground of divorce did not exist, and dismissed the petition.

Dr. William Gosse, who died at a nursing home in Boscombe on December 19 after a very long illness, was at one time an active worker in the British Medical Association. Born on November 13, 1860, in Lincolnshire, he studied medicine at Charing Cross Hospital after earlier education at University College, Aberystwyth, and qualified as M.R.C.S., L.R.C.P., in 1886. He took the Cambridge D.P.H. in 1890 and the Durham M.D. in 1902. From Charing Cross, where he had been house-surgeon, he went to Stillingbourne, and was in general practice there until he moved to Parkstone, Dorset, and became a member of the Bournemouth Division of the B.M.A. He was representative of his Division at the annual Meetings from 1903 to 1911, and for two years a member of the Central Council. A former colleague (B. T.) writes: "In 1908 I joined Dr. William Gosse in partnership, and after his retirement I appreciated how greatly he was respected in Stillingbourne, and that in his practice he was not only their doctor but also their friend. During the war he acted as medical officer of health for the borough of Poole. He was, both before and after his retirement, a very active member of the British Medical Association, and was always keenly interested in his old hospital, and endowed a bed there."

SOCIETY OF APOTHECARIES OF LONDON
The following candidates have passed in the subjects indicated:
Surgery.—G. R. Green, R. G. Titchhurst.
Medicine.—J. A. Bailey, N. P. Desai, C. R. Morgan, D. Specier, Forensic Medicine.—J. A. Bailey, N. P. Desai, C. R. Morgan, Midwifery.—J. A. Bailey, D. H. Dracup, D. S. Foster, A. B. Kennedy, G. E. King-Turner.
The diploma of the Society has been granted to J. A. Bailey, C. R. Morgan, and G. E. King-Turner.

Medical Notes in Parliament

Mr. Chamberlain announced on December 21, that the Committee stage of the Cancer Bill will be taken in the House of Commons on January 31.

The Marriage (Scotland) Bill was read a first time by the Commons on December 21.

In the House of Lords on December 20 the Marriage (Scotland) Bill, the Limitation Bill, the Housing (Financial Provisions) (Scotland) Bill, and the Census of Production Bill were read the third time and passed.

The second reading of the Bastardy (Blood Tests) Bill is set down in the House of Lords for February 8. That House stands adjourned till February 7 unless urgent business intervenes.

The Royal Assent was given on December 22 to the Expiring Laws Continuance Act and the Housing (Financial Provisions) (Scotland) Act.

Drunkenness.—Sir SAUL HORE stated on December 20 that from 1924 to 1932 there was a steep fall in the number of convictions for drunkenness. Since 1932 the figure had risen each year, though the total was substantially lower than in 1930. The question of what steps could be taken to elucidate the causes of the increase was engaging his attention.

Pasteurization.—Sir ERNEST GRAMM-LITTLE asked on December 22 whether, in view of the conflicting opinions still expressed with regard to the value of pasteurization, Dr. Elliot would cause a judicial inquiry to be made into this matter at the earliest opportunity so that a final and considered decision could be given. Dr. Elliot said in reply that the facts with regard to pasteurization were well known. The conflict was a matter of opinion. He did not think that any useful purpose would be served by taking the course suggested.

Occupational Therapy.—Miss RATTIBONE said on December 22 that two Commissioners of the Board of Control who visited Park Prewelt Mental Hospital in July, 1937, made an entry in the visitors book to the effect that they had been disappointed at the progress made in occupational therapy, and that little appeared to be done for those patients who were in need of occupational treatment. She asked whether Dr. Elliot was satisfied that the defect referred to in this entry either had not existed or had been remedied; and how often and on what dates Park Prewelt Hospital had been inspected since the date when this complaint was made. Dr. Elliot replied that he knew of the entry made in July, 1937. Two Commissioners of the Board of Control visited the hospital again on October 14, 1938, and reported that since the previous visit a welcome advance had been made in the development of occupational therapy. There were certain directions in which they suggested the possibility of further advance.

Cancer "Cures."—Mr. GROVES asked Dr. Elliot whether the cures of cancer by Mr. Rees Evans had been brought to his notice; and whether, in drawing up his plan for a cancer service, he considered any of the unorthodox treatments claimed to have numerous successes. Dr. Elliot replied on December 22 that Mr. Rees Evans's claims had been brought

Notes in Brief
In Scotland, during six months from May 1 to October 31, 297 persons were charged with drunkenness caused by methylated spirits, compared with 1,243 persons in the corresponding six months of 1937.

Milk in Schools.—On March 31, 1938, out of 29,223 public elementary school departments in England and Wales, 19,200 made no arrangements for the supply of milk. The department making no arrangements were for the most part small, and contained less than 3 per cent. of the total number of public elementary school children.

Midwives Act.—Dr. ELLIOT declared that, taking the different boroughs and counties in Wales, the Midwives Act of 1936 was fully operative in each of them. This was the first full year during which the service set up by the Midwives Act had been in operation. The maternal mortality rate for Wales in 1937 showed a welcome improvement over that in 1936, and he hoped the new service would contribute to the maintenance of that improvement.

Medical News

Mr. R. C. Emslie, M.S., F.R.C.S., has been appointed a member of the Royal Commission recently set up to inquire into the subject of workmen's compensation. The chairman of the Commission is Sir Hector James Wright Hetherington, L.L.D.

Professor Emilie de Grosz of Budapest will give an address on "The Surgery of the Eye in Hungary" at the Tenth Memorial Institute, Church Street, Glasgow, on Wednesday, January 18, at 8.15 p.m. The address has been arranged by the Department of Ophthalmology of the University of Glasgow, and all interested are invited to attend.

The Royal Sanitary Institute has arranged a discussion on "House Management: its Principles and Practice," to be opened by Dr. J. Greenwood Wilson, at 90, Buckingham Palace Road, S.W., on Tuesday, January 10, at 5.30 p.m.

The winter conversation of members of the University of London Medical Graduates Society and other medical graduates of the University of London was held at the Wellcome Research Institution by invitation of the Director-in-Chief, Dr. C. M. Wenyon, F.R.S., on December 15. The President, Sir James Wallon, received the guests, who included Sir StClair Thomson, the Foundation President of the Society, and a representative gathering, Dr. S. H. Dukes, Director of the Wellcome Museum of Medical Science, outlined the objects of the museum, the system of arrangement and recent developments, and led the visitors on an inspection of the exhibits. The annual meeting and dinner of the Society will be held in the Langham Hotel on Tuesday, May 2, 1939.

The issue of *La Riforma Medica* for November 5 is devoted to an illustrated account of the proceedings of the forty-fourth congress of the Italian Society of Internal Medicine and the forty-fifth congress of the Italian Society of Surgery, held simultaneously in Rome on October 19 to 22.

The International Association for the Prevention of Blindness has founded a new quarterly journal entitled *Journal of Social Ophthalmology*. Its offices are at 66, Boulevard Saint-Michel, Paris Vle.

Dr. Ross T. McIntire, White House physician, has been appointed Surgeon General of the U.S. Navy with the rank of rear-admiral, in succession to Admiral Percival S. Kossiter.

Although the epidemic of acute poliomyelitis in England and Wales is not finished the accompanying graph indicates that at the present rate of decrease it will be over early in the New Year. In comparison with 1937 the epidemic is characterized not only by its greater magnitude but by the occurrence of two readily discernible maxima and by the persistence of the disease in epidemic form into the cold months of the year. The last quarter of 1938 has been for the most part warm, and it remains to be seen whether the present spell of cold will lead to a rapid termination of the epidemic. There were nearly twice as many cases in 1938 as in 1937, but the numbers notified approximately in the second week of September of both years. The prevalence of the disease in Essex is largely responsible for the increase in 1938.

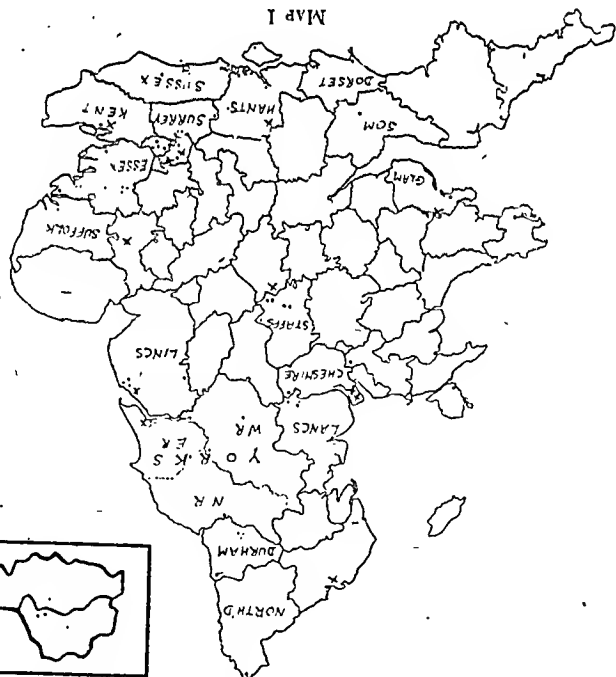

The Eugenics Society has arranged the following programme for 1959 at the Rooms of the Royal Society, Burlington House, Piccadilly, W., on Tuesday, at 5.15 p.m.: January

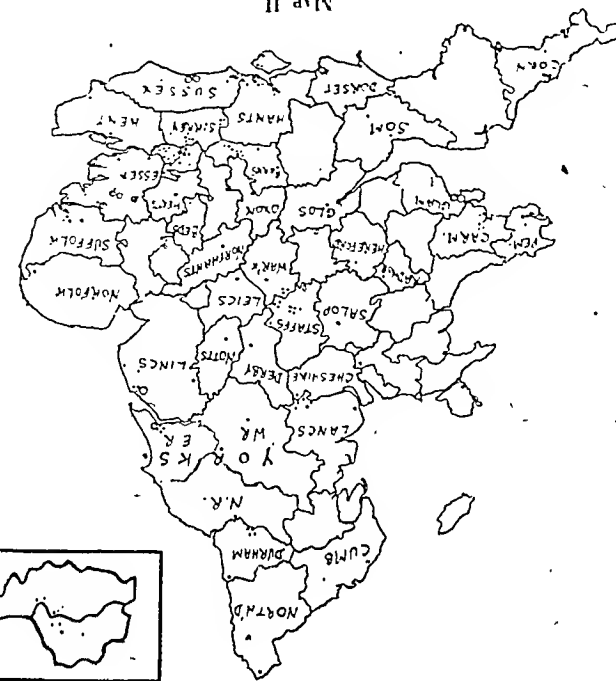

So far as can be judged, the spread of acute poliomyelitis in England and Wales results from the presence of multiple foci which appear to have little causal connexion with each other and are often at considerable distances apart. With the exception of the Essex outbreak the subsequent course of events for each individual focus is tolerably uniform: after the initial case two or three up to a dozen cases crop up at intervals over a period of 10 to 30 months or so, and a final crop may follow after an interval of several weeks, presumably due to the presence of carriers in the community. In the meantime a spread to neighbouring cities or counties has

already taken place, lighting up a fresh focus and leading to a similar train of events. There is little ground for believing that the exceptional prevalence of the disease in Essex is due to special circumstances, whether geographical or affecting the members of the communities involved by reason of lowered resistance, general or specific. It may well be that the epidemic was largely accidental, the result of a

the movement of contacts, usually with supervision for a prophylaxis being the avoidance of close congregation of susceptibles in affected communities and the restriction of injection of serum and the use of gargles and nasal sprays have played a secondary part, the most effective means of the disease might be well advanced. In these countries the America, Australia, and Denmark—methods of controlling

fortnight or so. In the epidemic briefly reviewed here it is probable that the application of administrative measures on these lines undertaken by local authorities with the co-operation of medical practitioners has been the main factor in securing the localization of the disease and the prevention of a major epidemic. The dots in the above maps represent single cases of poliomyelitis; the circles, five cases; and the circles with a dot inside, ten cases. The incidence in London is shown in the inset maps.

series of chances, or rather mischances, in which infection to lead to invasion and manifest disease. Coincident with the recognized cases subclinical infections and temporary carriers appear on a rising scale as the community is increasingly "sated." As the epidemic gathers force infection is introduced (usually by abortive cases and carriers) into more distant centres hitherto unexposed. If an answer could be given to the question why these local outbreaks do not usually develop into major epidemics, as in other countries—notably

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 17, 1938. Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns (125 in 1937) in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

† After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.

‡ Death from puerperal sepsis.

Letters, Notes, and Answers

All communications, in regard to editorial business should be addressed to the EDITOR, *British Medical Journal*, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The Telephone Number of the British Medical Association and the *British Medical Journal* is EUSTON 2111. The TELEGRAPHIC ADDRESSES are

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Athology* Westcott, London.
SECRETARY, *Medicisera Westcott, London*.
The address of the B.M.A. Scottish Office is 7, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumanan Docteur na h-Eirann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Gas-and-Air Analgesia in Midwifery

Dr. W. A. Clark (Glamorganshire) writes: (1) Has any fatality due to the use of gas in childbirth ever occurred? (2) What damage of any kind has ever been attributable to the use in labour? (3) What justification is there for the Central Midwives Board's insistence on the presence of (a) a specially trained midwife, and (b) another nursing assistant, at the labour of a woman who uses a gas-and-air apparatus for analgesia?

LETTERS, NOTES, ETC.

"New Intravenous Cannula"

Mr. Maurice Lee (London, W.1) writes: In the *Journal of December 24* (p. 1315) I notice a "new intravenous cannula" described by Mr. C. J. C. Siggers. I devised a cannula of a similar nature two years ago, and this was described and illustrated in the *Journal of October 10, 1936* (p. 718). The instrument has been used by me very successfully, and the principle is exactly the same in every respect as that described by Mr. Siggers. A picture of my cannula is also shown in Hamilton Bailey's *Emergency Surgery* (p. 3).

Inoculation against Diphtheria

Dr. W. L. English (Crewe) writes: On two occasions in the past I made inquiry in your columns as to the advisability of using an inoculation for diphtheria, while giving a prophylactic dose of serum. To my disappointment the query was ignored. I notice that you now refer to it in a leading article. Anyhow, in spite of my getting no encouragement from authority, I have been carrying on on my own. I certainly was rather amazed at the lack of interest in my question.

Chemiotherapy of Gonococcal Ophthalmia Neonatorum

Dr. C. MacKenzie (Ross-shire) writes recording a case similar to that described by Dr. F. J. T. Bowie (*Journal*, August 6, p. 283): The child was born on July 23, 1938, and on July 30 developed ophthalmia. Examination of a smear confirmed the diagnosis of gonococcal ophthalmia. A trained nurse carried out efficiently the treatment with boracic lotion and 10 per cent. argyrol, as prescribed, until August 22 with no improvement. From August 23 the child was given 0.25 grammes of M & B 693 three times a day; on August 25 there was a considerable improvement. There was very little discharge and the eye required no treatment during the night. For four further days the child was given

Social Pathology

Dr. Edward V. Bevan (Cambridge) writes: Thinking people must realize that whatever precautions are taken, and whatever of life and of property in every combatant country soon after the beginning of the next war. The medical profession in other countries is debating its own individual problems, in its own journals, in the same way as we are, with the same sort of pathetic mixture of practical suggestion and despair. Medicine, it seems to me, is international, and here are doctors discussing a problem selfishly, as individuals of separate countries. Is it not possible for the British Medical Association to approach the proper bodies in other countries—France, Germany, Italy, Russia, and others—with a view to calling a conference? If the medical profession could confer internationally on the subject of the management and prevention of war casualties, surely it would be a long step in the right direction—that of the peaceful settlement of international disputes.

Prevention of War

had similar cases.

Dr. Edward V. Bevan (Cambridge) writes: Thinking people must realize that whatever precautions are taken, and whatever of life and of property in every combatant country soon after the beginning of the next war. The medical profession in other countries is debating its own individual problems, in its own journals, in the same way as we are, with the same sort of pathetic mixture of practical suggestion and despair. Medicine, it seems to me, is international, and here are doctors discussing a problem selfishly, as individuals of separate countries. Is it not possible for the British Medical Association to approach the proper bodies in other countries—France, Germany, Italy, Russia, and others—with a view to calling a conference? If the medical profession could confer internationally on the subject of the management and prevention of war casualties, surely it would be a long step in the right direction—that of the peaceful settlement of international disputes.

Prolapsed Hand and Breech Presentation

Dr. Sybil S. Stein (Johannesburg) writes: As the following obstetrical condition appears to be rare, no mention of it appearing in the literature, it was considered worthy of being recorded. The patient, a well-built European woman, aged 40, with a history of ten very quick easy labours, began labour pains at 3 a.m. On examination of the fat pendulous abdomen at 8 a.m. the breech was felt lying at the brim. There was some right obliquity of the uterus; the head was not felt. A foetal heart was heard 1½ inches above and to the right of the umbilicus. On vaginal examination the internal os was two fingers dilated in front of the breech. In view of the fact that the patient had had twins twice previously the possibility of twins was considered, although the abdominal examination had negatived this. It was thought that possibly the prolapsed hand belonged to a second foetus lying posterior to the breech and presenting as a vertex. The hand was replaced above the breech to permit the latter to engage, and then labour was allowed to proceed. Labour was protracted, though the contractions were good and meconium was passing in the liquor at 5.30 p.m.; the foetal heart was good, but the breech was still not engaged. Vaginal examination was repeated, and the whole arm to the middle of the humerus was found prolapsed in front of the breech. It was again replaced and the extended legs were brought down through the cervix. With the next few pains the feet and legs now rotated backwards, so that the abdomen of the foetus appeared at the vulva, followed rapidly by the body, which faced upwards. There was then some delay, so the extended arms were brought down (one was behind the head) and the body was gently turned through the rest of a complete circle and the head was delivered easily with slight jaw and shoulder traction. The child was somewhat asphyxiated but responded rapidly to treatment. The placenta then gave cause for anxiety, for after waiting two hours the patient began to bleed in gushes. Crotch's method was tried unsuccessfully, so the partially adherent placenta was removed manually. The patient and her baby progressed excellently and were discharged on the tenth day. The baby weighed 7½ lb., and the arm from the tip of the shoulder to the tip of the middle finger measured 8½ inches, which does not appear to be unduly long in comparison with the baby's total length of 21½ inches. The interest lies in (1) the unusual presentation—prolapse of hand and arm in front of the breech; and (2) the spontaneous backward rotation of the foetus. I should be interested to know if others have

Physiological Bullness of Right Apex, R. W. Hick.—p. 615.

Physiological Bullness of Right Apex.—This is an interesting historical investigation of the conception, widely held in America and less so in Britain and on the Continent, that the right apex normally yields a duller percussion note than does the left. The author concludes that this is a concept of American clinicians not based upon, or justified by, objective experimental results.

Some Rules of Endocrine Surgery: Surgery of Sympathetic System and Endocrine Surgery, R. Leriche.—p. 1537.

Present-day Indications for Phrenectomy in Treatment of Pulmonary Tuberculosis, J. Vallis and N. Tsoutsis.—p. 1539.

Endocrine Surgery.—Leriche discusses the pathology of the endocrine glands and their relation to the sympathetic system, and gives examples illustrating certain rules which he has found helpful in the practice of endocrine and sympathetic surgery.

Phrenectomy.—After a brief historical resume of the rise and fall in popularity of this operation since it was first advocated by Stuerz in 1911, the authors briefly consider the indications for and contraindications to phrenectomy in the treatment of pulmonary tuberculosis. They come to the conclusion that its applications are very limited—for example, in early lesions of a non-caseous nature situated at the base and near the mid-line rather than at the periphery. It may also be used as a complementary operation after an artificial pneumothorax of the type known as pneumothorax *à cord*—that is, where a fairly good collapse is obtained from side to side but not from above downwards owing to the constricting action of the diaphragm. Phrenectomy may also be used after thoracoplasty when there are active lesions at the base which are not sufficiently controlled.

Repeated Perforation of Gastric-duodenal Ulcers: Two Unpublished Cases, J. Gossel, M. Jouanneau, and J. Allmand.—p. 1556.

Angina and 883 F.—The authors give the results of their treatment of thirty-two cases of angina, etc., with this drug (dichloramino-methyl-benzodioxan). The cases were all followed for several months and had previously tried all the usual forms of treatment without avail: 883 F was found to be a very useful symptomatic remedy for the pain of angina and one which could be continued for long periods without ill effects other than slight gastric disturbances easily remedied by means of alkalis.

Repeated Perforation.—The authors discuss the frequency, pathology, treatment, and prophylaxis of repeated perforation in cases of gastric and duodenal ulceration and quote sixty-six cases.

Katharine Kays made her report on the treatment of the breast in the German War. I. Lohrke—p. 1145.
The treatment of the breast in the German War. I. Lohrke—p. 1145.

Neurotic Disease and Hysteria. W. Bäumler—p. 1150.

Production of Breast.—Wirths irradiated the breasts of fifty-eight nursing mothers with too little milk secretion or with a history of previous difficulty in nursing. Five-minute sittings increasing to ten minutes were begun on the second to the fifth day of the puerperium. In fifty-one mothers the increase of milk was marked. In seven cases irradiation was not begun before the eighth day.

Acute Nicturine Poisoning.—Two personal cases and others from the literature are described. The symptoms are not characteristic, so that the diagnosis depends chiefly on chemical or biological detection of nicotine in the excreta. Cases of acute nicotine poisoning are known, although they are less frequent than chronic or narcotic cases, and have been recorded in workers in factories producing solutions used in orchards or vineyards.

Thermometer of Adipose Tissue with Urinary (F.). L. Lundh—p. 428.

Parathyroid and Body Temperature.—In four cases of hyperparathyroidism (generalized osteitis fibrosa) the variations in the body temperature were studied. An elevation above the normal level is not uncommon. It disappeared immediately after the removal of the parathyroid adenoma, and is therefore probably caused by the metabolic disturbances inherent in the disease.

- Modern Conception of Gastric Secretory Functions Based upon Recent Investigations and Newer Interpretations.** S. Morrison.—p. 617.
- Haemorrhagic Tendency in Jaundice.—Oral administration of vitamin K prepared from putrefied fish meal, with bile salts or human bile obtained from a biliary fistula, increases the concentration of prothrombin and thereby reduces the clotting time of the blood.**
- Therapeutic Agents and Bile.**—Using improved methods, the authors have investigated the effects on bile secretion of a high fat diet, bile salt preparations, and certain drugs. Linseed oil in the diet increased the output of cholesterol and biliary lipids, as well as the quantity of bile. The conjugated bile acid preparations are superior to the unconjugated in stimulating the flow of bile containing increased amounts of biliary constituents. Saturated bile acid increased the output of bile, while various other drugs, including calcium, were without effect. Sphinganine had no effect on the secretion of bile, but appeared in the bile in concentrations bacteriostatic for certain organisms.
- Gastric Secretion.**—Neutral red is excreted into the stomach by the oxyntic cells and this forms a useful test of the integrity of these cells. Using this fact as a basis for his experiments Morrison offers the hypothesis that a pyloroduodenal hormone may control oxyntic-cell activity. The pylorus and duodenum also provide an anti-pernicious anaemia factor. These activities are probably related to one another. An attempt is made to demonstrate an interrelationship between all gastric secretions, including that of the intrinsic factor.

—p. 207.

Factors of Resistance to Oxygen Want in the Rat's Lung. J. A. G. REID.
—p. 211.

Resistance to Oxygen Want.—Rats on a pure carrot diet exhibit increased resistance to oxygen want. A synthetic diet containing rice-starch mainly, with yeast, water, and 25 per cent. cellulose, gives some similar protection. Protein enhances the ill effects of oxygen want, and it is suggested that patients with oxygen want should be given diets of low protein content and containing carrot, parsnip, or beetroot.

Experimental Hypertension.—The presence of ischaemic renal tissue (dog) is an indispensable condition for the development of hypertension, some substance being formed which escapes into the general circulation. Increased dietary loads elicit reversible rises in the blood-pressure level of hypertensive dogs. Urea and meat are equally potent and sodium chloride still more effective; with the latter oedema and convulsive "uraemia" have been produced. When interference with the renal blood supply is very severe a syndrome resembling that known as convulsive "uraemia" is observed.

ANÆSTHETIC

has been shown to possess **CONSPICUOUS ADVANTAGES** over other local anaesthetics

Percaine has become so firmly established within the last few years that there are over

2,000 PUBLISHED REFERENCES

to its pharmacological properties and uses in

all fields of surgical practice.

TOXICITY in minimal effective concentrations less than that of either cocaine or procaine (1, 2).

DURATION of action greatly exceeds that of either cocaine

or procaine (3, 4, 5, 6, 7, 8, 9, 10, 11, 12).

ONSET approximately as rapid as with cocaine or procaine (3, 4).

IRRITATION of the tissues

DELAY in healing completely absent (3, 4, 13, 14, 15, 16, 17, 18, 19, 20, 21).

AFTER-PAIN abolished or materially reduced (3, 5, 14, 15, 16, 22, 23).

FALL IN BLOOD-PRESSURE in spinal anaesthesia considerably less than with procaine (20, 24, 25, 26, 29).

COMPLETELY REPLACES cocaine in surface anaesthesia and is free from the major disadvantages of cocaine (7, 21, 28).

THE PERCAINE HANDBOOK

A comprehensive and fully documented 52-page survey of the Pharmacology, Toxicology and Clinical Applications of Percaine will be sent on request.

Nearest Station: WICKHAM MARKET.
Postal Address: WOODBRIDGE, SUFFOLK.

BOWDEN HOUSE,

NARROW-OX-FIELD HILL,

For the residential treatment of Functional Nervous Disorders

No case under certificate nor under the M.T.A.
This home, which was founded in 1911, is designed to provide for psychoneurotics a curative environment associated with modern psychological treatment modified to suit each individual patient. The treatment is in the hands of three experienced psychotherapists, and most patients receive three hours of analytical treatment per week. Occupational-therapy of many varieties is available but not obligatory. Recreations include tennis, badminton, billiards, etc.
On admission patients are examined by the diagnostic physician, who advises on all physical treatment. As far as possible all necessary pathological examinations are carried out by the pathologist in the laboratory on the premises.

STAFF:

H. CRICHTON-MILLER, M.A., M.D., M.R.C.P. (Senior Physician). GRACE H. NICOLE, M.A., M.B. (Resident Physician).
ALFRED TORRIS, M.A., M.B., Ch.B., D.P.M. (Medical Superintendent). MARY HALL, M.B., B.Ch. (Pathologist).

A Private Hospital or Clinic for the diagnosis and treatment of Internal Diseases (except Mental or Infectious Diseases). The Clinic is provided with a full staff of doctors, bacteriologists, chemists, radiologists, dietitians, nurses, masseurs, and masseuses.

The surroundings are beautiful. The climate is mild. There is central heating throughout. The annual rainfall is 30.5 inches, that is, less than the average for England.

The inclusive weekly fees are from 15 guineas a week, according to the room occupied; rooms with bathroom are from 21 guineas. The charges include all chemical, bacteriological, X-ray or other examination advised by the doctors, and all the usual forms of treatment, in addition to board and lodging. There are no extra charges except for alcohol (when ordered) and laundry. An examination and consultation fee of 15 guineas is charged on the first visit.

Address: The Secretary, Ruthin Castle, North Wales.

Telegrams: Castle, Ruthin. Telephone: Ruthin 66.

RUTHIN CASTLE, NORTH WALES

ROYAL NAVAL MEDICAL SERVICE

DEC. 31, 1938

THE BRITISH MEDICAL JOURNAL

34

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry at the end of March, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list. Marriage Allowance is paid under the same conditions as for other Naval Officers.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1939.

Appointments for Medical Officers in the ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force. Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry.

The period of service is 3 years—extendible to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study. Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission up to twelve months is allowed for appointments held at approved hospitals.

Fuller information can be obtained from The Director of Medical Services, Air Ministry, Kingsway, London.

THIS MOST HELPFUL SERVICE IS GAINING FAVOUR AMONGST MEDICAL MEN THROUGHOUT THE COUNTRY.

ALL TRANSACTIONS STRICTLY CONFIDENTIAL

THE PATIENT'S INSISTENT NEED

Pain is the dominant symptom which induces the majority of patients to seek medical aid; hence the practitioner's reputation depends in no small degree upon his skill in relieving pain. For this he cannot have a more reliable ally than Veganin.

Veganin presents a synergistic combination of acetylsalicylic acid, phenacetin and codeine and is considered one of the safest analgesics. It is quickly absorbed and its action is prompt and prolonged.

Veganin affords effective relief in a vast number of painful conditions and alleviates the nervousness that so frequently accompanies them. There is no aftermath of languor and no systemic disturbance.

VEGANIN

TABLETS

Made in England

WILLIAM R. WARNER
& CO., LTD.
POWER ROAD, CHISWICK
LONDON W.4

A supply for clinical trial sent on request.

dispensing.

Supplied in tubes of 10 and 20; boxes of 100, 500 and 1,000 for

to the public.

Veganin Tablets are not advertised

Veganin has proved particularly serviceable in the treatment of headaches, migraine, rheumatic affections, post-operative and post-puerperal pain, in the backache and muscular pains of influenza.

INDICATIONS—

Out of the
Shadow of Pain
